PRODUCT WARRANTY

Analytical Technology, Inc. (Manufacturer) warrants to the Customer that if any part(s) of the Manufacturer's equipment proves to be defective in materials or workmanship within the earlier of 18 months of the date of shipment or 12 months of the date of start-up, such defective parts will be repaired or replaced free of charge. Inspection and repairs to products thought to be defective within the warranty period will be completed at the Manufacturer's facilities in Collegeville, PA. Products on which warranty repairs are required shall be shipped freight prepaid to the Manufacturer. The product(s) will be returned freight prepaid and allowed if it is determined by the manufacturer that the part(s) failed due to defective materials or workmanship.

This warranty does not cover consumable items, batteries, or wear items subject to periodic replacement including lamps and fuses.

Gas sensors carry a 12 months from date of shipment warranty and are subject to inspection for evidence of misuse, abuse, alteration, improper storage, or extended exposure to excessive gas concentrations. Should inspection indicate that sensors have failed due to any of the above, the warranty shall not apply.

The Manufacturer assumes no liability for consequential damages of any kind, and the buyer by acceptance of this equipment will assume all liability for the consequences of its use or misuse by the Customer, his employees, or others. A defect within the meaning of this warranty is any part of any piece of a Manufacturer's product which shall, when such part is capable of being renewed, repaired, or replaced, operate to condemn such piece of equipment.

This warranty is in lieu of all other warranties (including without limiting the generality of the foregoing warranties of merchantability and fitness for a particular purpose), guarantees, obligations or liabilities expressed or implied by the Manufacturer or its representatives and by statute or rule of law.

This warranty is void if the Manufacturer's product(s) has been subject to misuse or abuse, or has not been operated or stored in accordance with instructions, or if the serial number has been removed.

Analytical Technology, Inc. makes no other warranty expressed or implied except as stated above.

Part 1 - Introduction

1.1 General

The Model Q45C2 Portable Conductivity monitor/analyzer provides an extremely versatile measurement system for monitoring and control of conductivity over the range of 0.056 µS/cm to 2000 µS/cm. The instrument may be programmed to display either Conductivity or Resistivity.

The system operates on two AA batteries, and will run continuously for approximately 240 hours.

**Warning:** If unit is to be stored for more than 6 months REMOVE the batteries from the holder to avoid potential damage from battery leakage.

The Q45C2 portable displays conductivity and sensor temperature. The instrument may be used with Q25C2 sensors with cell constant of 0.05K for low range measurements and 0.5K cell constant of 0.5K for higher conductivity measurements. The following is a list of ranges and the sensor that may be used for each range.

- **Resistivity:**
  - 0.00 to 20.00 MΩ / with 0.05K cell constant
  - 0.0 to 200.0 kΩ / with 0.05K cell constant

- **Conductivity:**
  - 0.000 to 2.000 µS/ with 0.05K cell constant
  - 0.0 to 20.00 µS/ with 0.05K or 0.5K cell constant
  - 0.0 to 200.0 µS/ with 0.05K, 0.5K cell constant
  - 0 to 2000 µS/ with 0.5K cell constant

1.2 Features

- Standard Q45C2 electronic transmitters are designed to be a fully isolated, battery operated instrument. The monitor can be quickly converted to either a loop power transmitter or line powered analyzer.

- Two 10-bit, isolated, 0-2.5 VDC analog outputs may be configured to track conductivity and temperature. Both analog outputs can be individually programmed to fail to specific values.

- Large, high contrast, custom Super-Twist display provides excellent readability. The secondary line of display utilizes 5x7 dot matrix characters for clear message display. Two of four measured parameters may be on the display simultaneously. An LED backlight can be turned on if necessary for use in very low light conditions.
- Sensor diagnostics monitor electrode coating/fouling, sensor leaks, and RTD condition. Diagnostic messages provide a clear description of any problem with no confusing error codes to look up. Messages are also included for diagnosing calibration problems.

- Quick and easy one-point calibration method and sensor zero-cal. To provide high accuracy, all calibration methods include stability monitors that check temperature and main parameter stability before accepting data.

- Selectable Pt1000 or Pt100 temperature inputs. Systems can also be hard-configured for three-wire elements. Temperature element can be user calibrated.

- Security lock feature to prevent unauthorized tampering with transmitter settings. All settings can be viewed while locked, but they cannot be changed.

Part 2 – Instrument Configuration

2.1 General

The Q45C2 Portable Conductivity System comes complete with a specially designed handle that allows the system to be comfortably carried, or quickly strapped to a railing. Although the system is designed to be a portable system, it can be permanently mounted for longer term field use. This is possible due to the very long battery life spans that can be achieved with the system.

2.2 Portable Handle

A removable handle is included with each unit that provides not only comfortable transportation of the system, but the integral locking strap allows the system to be quickly mounted to pipes or rails for longer term use in one area.

Figure 1 - Portable Handle - Views
Part 3 – Electrical Installation

3.1 General

The sensor cable can be quickly connected to the Q45 terminal strip by matching the wire colors on the cable to the color designations on the label in the monitor. Keep signal cable away from AC power lines, adjustable frequency drives, motors, or other noisy electrical signal lines.

3.2 Direct Sensor Connection

The sensor cable should be routed into the enclosure through the right hand cord grip on the bottom of the enclosure. Make sure the cord-grips are snugly tightened after electrical connections have been made to prevent moisture incursion. When stripping cables, leave adequate length for connections in the transmitter enclosure, as shown below.

![Figure 2 - Sensor Cable Preparation](image-url)
3.3 Sensor Connections

Figure 3 - Sensor Connections

Note: Wiring for Sanitary Sensors is identical to standard sensor wiring.

O & M Manual
Rev-F (7/15) - 10 -
3.4 OEM Sensor Connections

**Figure 4 - OEM Sensor Connections**
4.1 General

To turn the system ON, simply press and hold the MENU key for approximately 5 seconds and the display will come on. **To turn the unit off, press and hold the ENTER key until the display shuts off (about 3 seconds).** Note that the unit must be in the MEASURE menu in order for the 3-second key press to operate. The instrument will turn off automatically after 30 minutes if no keys are pressed – optimizing battery life. This mode of operation is ideal for portable operation where intermediate readings are being taken. Assuming the instrument is used perhaps an hour per day, this would result in a battery lifespan of about 240 hours. For continuous operation with no automatic shut-off, turn the Auto-OFF feature to OFF in the DIAG menu. This mode is intended for use when the instrument outputs are used for transmitting data. In this mode, the instrument will run continuously until the battery reaches the shut-down level (1.6V). It should be noted that rechargeable AA batteries reduce operational times dramatically, as they typically contain much less energy than standard batteries.

The PWR switch disconnects the AA batteries and is only used to disconnect the battery if the system is not to be used for a long period of time (> 3 months of storage). Otherwise, leave this switch in the ON position. The red dip switch is only for factory use.

The "B" will flash on the display next to the main measurement indication when the instrument requires battery replacement. If the battery is not replaced, eventually the unit may not turn on in the normal operating mode. Once the low battery condition is indicated, the instrument will only stay powered for 10 minutes.

4.2 Battery / Power Circuit Board

Q45C2 monitors are powered by internal AA alkaline batteries Figure 5 shows this board assembly with batteries installed.

The battery circuit board contains 3 switch assemblies as shown in the drawings.
The first (S1) is an On/Off slide switch. This switch must be in the ON position for operation. Turn it to OFF if you do not intend to operate the monitor in the next week or two.

The second switch assembly (S2) contains two switches, the one on the left marked LOCK and the one on the right marked MODE. The function of these two slide switches are as follow:

**LOCK**

This switch is used to define how the monitor will turn on and off. This switch is normally in the OFF position. With the lock switch off, the monitor will be turned on manually using the MENU key on the front of the monitor. With the lock switch in the ON position, the monitor will always be on when there is enough power to run the monitor. The ON position is normally used when operating from an external power supply intended for continuous operation.

**MODE**

This switch is used to set the voltage at which monitor will shut off when powered by internal batteries. Alkaline batteries can normally be run down to about 0.8 volts. When using alkaline batteries, the mode switch is in the OFF position (factory default). If rechargeable NiMH batteries are substituted, place the MODE switch in the ON position. Note that rechargeable NiMH batteries have only about 35% of the capacity of an alkalines. However, NiMH batteries can be recharged hundreds of times.
The third switch assembly is a single slide switch (S3) which defines whether the 0-2.5 VDC signals from the monitor are isolated or non-isolated. Output isolation is not required when outputs are connected to the internal data logger. However, if the outputs are connected to external devices through the external connection cable, putting this switch in the ISO position will protect against possible ground loops. The isolation circuit will slightly increase the power requirement for the monitor, resulting in a bit less battery life.

4.3 Battery Power Circuit Board

The Q45 portable instrument is primarily operated by software settings. However, there are also a few hardware details on the battery circuit board to note.

The battery board is a circuit board that sits in the rear of the Q45 enclosure, and connects to the Q45 AUX port through a ribbon cable. The battery board contains the battery clip for the two AA batteries and the output terminal strip for the two 0-2.5 VDC outputs. Along the left side below the ribbon cable is an ON/OFF slide switch. This switch can be used to turn the instrument completely OFF when not intending to use the unit for an extended period.

4.4 Voltage Outputs

There are two analog voltage outputs on the battery board with a terminal strip located in the lower right corner. The outputs are 0-2.5 VDC and may be used to send isolated data to remotely located recorders, PLC’s, etc. Output #1 is used only for conductivity, and Output #2 can be used for either temperature or pH (if the optional pH sensor is used). Output 2 can also be set for conductivity, Mg/L, or Temperature.
4.5 User Interface

The user interface for the Q45 Series instrument consists of a custom display and a membrane keypad. All functions are accessed from this user interface (no internal jumpers, pots, etc.).

Figure 6 - User Interface
4.6 Keys

All user configurations occur through the use of four membrane keys. These keys are used as follows:

**MENU/ESC**  To scroll through the menu section headers or to escape from anywhere in software. The escape sequence allows the user to back out of any changes in a logical manner. Using the escape key aborts all changes to the current screen and backs the user out one level in the software tree. The manual will refer to this key as either MENU or ESC, depending upon its particular function. In the battery-powered version of the Q45, this is also the ON button.

**UP (arrow)**  To scroll through individual list or display items and to change number values.

**LEFT (arrow)**  To move the cursor from right to left during changes to a number value.

**ENTER**  To select a menu section or list item for change and to store any change.

4.7 Display

The large custom display provides clear information for general measurement use and user configuration. There are three main areas of the display: the main parameter display, the secondary message line, and the icon area.

**Main Parameter**  During normal operation, the main parameter display indicates the present process input with sign and units. This main display may be configured to display any of the main measurements that the system provides. During configuration, this area displays other useful set-up information to the user.

![Display Example](image.png)
Lower Line

During normal operation, the lower line of the display indicates user-selected secondary measurements that the system is making. This also includes calibration data from the last calibration sequence and the transmitter model number and software version. During configuration, the lower line displays menu items and set-up prompts to the user. Finally, the lower line will display error messages when necessary. For a description of all display messages, refer to Section 7.3.

Icon Area

The icon area contains display icons that assist the user in set-up and indicate important states of system functions. The CAL, CONFIG, and DIAG icons are used to tell the user what branch of the software tree the user is in while scrolling through the menu items. This improves software map navigation dramatically. Upon entry into a menu, the title is displayed (such as CAL), and then the title disappears to make way for the actual menu item. However, the icon stays on.

HOLD

The HOLD icon indicates that the analog output of the transmitter has been put into output hold. In this case, the output is locked to the last input value measured when the HOLD function was entered. HOLD values are retained even if the unit power is cycled.

FAIL

The FAIL icon indicates that the system diagnostic function has detected a problem that requires immediate attention. This icon is automatically cleared once the problem has been resolved.
4.8 Software

The software of the Q45C is organized in an easy to follow menu-based system. All user settings are organized under five menu sections: Measure, Calibration [CAL], Configuration [CONFIG], Control [CONTROL] and Diagnostics [DIAG].

Note: The default Measure Menu is display-only and has no menu icon.

4.9 Software Navigation

Within the CAL, CONFIG, CONTROL, and DIAG menu sections is a list of selectable items. Once a menu section (such as CONFIG) has been selected with the MENU key, the user can access the item list in this section by pressing either the ENTER key or the UP arrow key. The list items can then be scrolled through using the UP arrow key. Once the last item is reached, the list wraps around and the first list item is shown again. The items in the menu sections are organized such that more frequently used functions are first, while more permanent function settings are later in the list. See Figure 4-4 for a visual description of the software.

Each list item allows a change to a stored system variable. List items are designed in one of two forms: simple single variable, or multiple variable sequences. In the single variable format, the user can quickly modify one parameter - for example, changing temperature display units from °F to °C. In the multiple variable sequence, variables are changed as the result of some process. For example, the calibration of conductivity generally requires more than one piece of information to be entered. The majority of the menu items in the software consist of the single variable format type.

Any data that may be changed will be flashing. This flashing indicates user entry mode and is initiated by pressing the ENTER key. The UP arrow key will increase a flashing digit from 0 to 9. The LEFT arrow key moves the flashing digit from right to left. Once the change has been completed, pressing ENTER again stores the variable and stops the flashing. Pressing ESC aborts the change and also exits user entry mode.

The starting (default) screen is always the Measure Menu. The UP arrow key is used to select the desired display. From anywhere in this section the user can press the MENU key to select one of the four Menu Sections.

The UP arrow icon next to all list items on the display is a reminder to scroll through the list using the UP arrow key.

To select a list item for modification, first select the proper menu with the MENU key. Scroll to the list item with the UP arrow key and then press the ENTER key. This tells the system that the user wishes to perform a change on that item. For
single item type screens, once the user presses the ENTER key, part or all of the variable will begin to flash, indicating that the user may modify that variable using the arrow keys. However, if the instrument is locked, the transmitter will display the message **Locked!** and will not enter user entry mode. The instrument must be unlocked by entering the proper code value to allow authorized changes to user entered values. Once the variable has been reset, pressing the ENTER key again causes the change to be stored and the flashing to stop. The message **Accepted!** will be displayed if the change is within pre-defined variable limits. If the user decides not to modify the value after it has already been partially changed, pressing the ESC key aborts the modification and returns the entry to its original stored value.

In a menu item which is a multiple variable sequence type, once the ENTER key is pressed there may be several prompts and sequences that are run to complete the modification. The ESC key can always be used to abort the sequence without changing any stored variables.

![Software Map](image-url)

**Figure 7 - Software Map**
4.10 Measure Menu [MEASURE]

The default menu for the system is the display-only menu MEASURE. This menu is a display-only measurement menu, and has no changeable list items. When left alone, the instrument will automatically return to this menu after approximately 30 minutes. While in the default menu, the UP arrow allows the user to scroll through the secondary variables on the lower line of the display. A brief description of the fields in the basic transmitter version is as follows:

**TRANSMITTER MEAS SCREENS:**

- **25.7°C**
  Temperature display. Can be displayed in °C or °F, depending on user selection. A small “m” on the left side of the screen indicates the transmitter has automatically jumped to a manual 25°C setting due to a failure with the temperature signal input.

- **#1 Vout**
  Instrument Output Signal #1

- **#2 Vout**
  Instrument Output Signal #2

- **Cell**
  Sensor cell factor used for calibrating system without the use of calibration solutions.

- **Q45C2 vX.XX**
  Transmitter software version number.

**Note:** A display test (all segments ON) can be actuated by pressing and holding the ENTER key while viewing the model/version number on the lower line of the display.

The MEASURE screens are intended to be used as a very quick means of looking up critical values during operation or troubleshooting.
4.11 Calibration Menu [CAL]

The calibration menu contains items for frequent calibration of user parameters. There are three items in this list: Cal Cond, Cal Temp, and Cal TC Factor.

Cal Cond

The conductivity calibration function allows the user to adjust the transmitter offset and span reading to match reference buffers, or to adjust the sensor offset to match the sample reading. See Part 5 - Calibration for more details.

Cal Temp

The temperature calibration function allows the user to adjust the offset of the temperature response by a small factor of ±5 °C. The temperature input is factory calibrated to very high accuracy. However, long cable lengths and junction boxes may degrade the accuracy of the temperature measurement in some extreme situations. Therefore, this feature is provided as an adjustment. See Part 5 - Calibration for more details.

Cell Const

This function allows the user to directly enter the factory measured cell constant for the Q25C2 sensor. When this feature is used, calibration with reference solutions is not necessary. See Part 5 - Calibration for more details.

Set Range

This function allows the user to set the display range of the transmitter for a specific application. Once set, all output functions use this display range to establish configuration settings. Press ENTER to initiate user entry mode, and the value will flash. Use the arrow key to modify the range for the desired range and then press ENTER.

Cal Zeros

This function calibrates all range zero-points to the specific sensor being used. This function is only required to be performed once at initial start-up or when the sensor has been replaced. See Part 5 - Calibration for more details.
4.12 Configuration Menu [CONFIG]

The Configuration Menu contains all of the general user settings:

**Entry Lock**
This function allows the user to lock out unauthorized tampering with instrument settings. All settings may be viewed while the instrument is locked, but they cannot be modified. The Entry Lock feature is a toggle-type setting; that is, entering the correct code will lock the transmitter and entering the correct code again will unlock it. The code is preset at a fixed value. Press ENTER to initiate user entry mode and the first digit will flash. Use arrow keys to modify value. **See end of manual for the Q45C2 lock/unlock code.** Press ENTER to toggle lock setting once code is correct. Incorrect codes do not change state of lock condition.

**Set Delay**
The delay function sets the amount of damping on the instrument. This function allows the user to apply a first order time delay function to the conductivity measurements being made. Both the display and the output value are affected by the degree of damping. Functions such as calibration are not affected by this parameter. The calibration routines contain their own filtering and stability monitoring functions to minimize the calibration timing. Press ENTER to initiate user entry mode, and the value will flash. Use the arrow keys to modify value; range is 0.1 to 9.9 minutes. Press ENTER to store the new value.

**Contrast**
This function sets the contrast level for the display. The custom display is designed with a wide temperature range, Super-Twist Nematic (STN) fluid.

The STN display provides the highest possible contrast and widest viewing angle under all conditions. Contrast control of this type of display is generally not necessary, so contrast control is provided as a means for possible adjustment due to aging at extreme ranges. In addition, the display has an automatic temperature compensation network. Press ENTER to initiate user entry mode, and the value will flash. Use arrow keys to modify the value; range is 0 to 8 (0 being lightest). Press ENTER to update and store the new value.
**Main Display**

This function allows the user to change the measurement in the primary display area. The user may select between conductivity, sensor temperature, or output current. Using this function, the user may choose to put temperature in the main display area and conductivity on the secondary, lower line of the display. Press ENTER to initiate user entry mode, and the entire value will flash. Use the UP arrow key to modify the desired display value. Press ENTER to store the new value.

**Select TC**

This function allows the user to select either a Pt1000 or Pt100 platinum RTD temperature element. The Pt1000 element is the standard element in all high performance Q25 sensors; it is the recommended temperature sensing element for all measurements. The Pt100 selection is provided as an alternative for use with existing combination-style sensors. Press ENTER to initiate user entry mode, and the entire value will flash. Use the UP arrow key to modify the desired value. Press ENTER to store the new value.

**Temp Mode**

This function sets the temperature compensation algorithm for the instrument. The following choices are available: **Lin**, **1 Tbl**, and **2 Tbl**.

- **Lin**: Linear temperature compensation method. This is the most common method and is recommended for most aqueous solutions. The slope for this method is set in the **Linear Comp** section.

- **1 Tbl**: Ammonia compensation method. This method is specific only to ammonia measurement.

- **2 Tbl**: Natural Water compensation method. This setting is limited to the temperature range of 0 - 35 °C.

**NOTES:**

1. Do not set the Temp Mode to a value other than **Lin** unless the instrument is specifically intended to measure one of the compounds listed above.

2. If Temp Mode is set to **1 Tbl** or **2 Tbl**, the settings for **Linear Comp** and **Ref Temp** will not appear in the Software Menu.
This selection is critical for control of the internal diagnostics and compensation factors. Press ENTER to initiate user entry mode, and the entire value will flash. Use the UP arrow key to modify the desired value.

**Solu Comp**

This function sets the correction slope value for the linear temperature compensation method and is used when the “Temp Mode” is set to **Lin**. Linear compensation is the method recommended for most aqueous solutions, and the value is typically 2.00 %/°C (25°C reference temperature) for neutral water. This is the factory default and it provides the best compensation for most aqueous solutions. Other typical ranges include:

- Acids: 1.0 to 1.6%/°C
- Bases: 1.8 to 2.0%/°C
- Salts: 2.2 to 3.0%/°C

**NOTE:** If the temperature units are changed between °C and °F (see Temp Units in this Section), the default setting for this output will change between 2.00 %/°C and 1.11%/°F accordingly.

Other compensation slopes for uncommon solutions may be found in chemical handbooks (such as the CRC). Press ENTER to initiate user entry mode, and the entire value will flash. Use the arrow keys to modify the desired value; entry range is 0.000%/°C (no compensation) to 4.000%/°C. Press ENTER to store the new value.

**Ref Temp**

The reference temperature function sets the basis point for the linear temperature compensation methods. In most cases this setting should be left at the default of 25.0 °C.

Press ENTER to initiate user entry mode, and the entire value will flash. Use the arrow keys to modify the desired value; range is 0.0°C to 50.0°C. Press ENTER to update and store the new value. This setting appears in the Software Menu only if “Temp Mode” is set to **Lin**.

**TDS Factor**

This function sets the linear relationship of the TDS (total dissolved solids) reading to the conductivity measurement. The actual units for the slope are in mg/L/μS. The default value is 00.49 mg/L/μS.
Press ENTER to initiate user entry mode, and the entire value will flash. Use the arrow keys to modify the desired value; range is 00.00 mg/L/μS to 99.99 mg/L/μS. Press ENTER to update and store the new value.

**Out 2 Mode**

This assigns the 4-20 mA output # 2 to Temperature (by selecting 1), μS (by selecting 2) or mg/L (by selecting 3)

**Temp Units**

This function sets the display units for temperature measurement. Press ENTER to initiate user entry mode, and the entire value will flash. Use the UP arrow key to modify the desired display value. The choices are °F and °C. Press ENTER to store the new value.

4.13 Control Menu [CONTROL]

The Control Menu contains all of the output control user settings:

**Set 0V #1**

**Set 2.5V #1**

**Set 0V #2**

**Set 2.5V #2**

These functions set the output range for each of the two instrument outputs. The value stored for the 0V point may be higher or lower than the value stored for the 2.5V point.

The entry values are limited to values within 40.00 ppm and must be separated by at least 1% of this range. Use the LEFT arrow key to select the first digit to be modified. Then use the UP and LEFT arrow keys to select the desired numerical value. Press ENTER to store the new value.

Output #1 will always be in units of ppm, as it is fixed to track dissolved oxygen. Output #2 will be in either units of ppm or C/F, depending on whether dissolved oxygen or temperature is set for Out#2 in the CONFIG menu.
4.14 Diagnostics Menu [DIAG]

The diagnostics menu contains all of the user settings that are specific to the system diagnostic functions, as well as functions that aid in troubleshooting application problems.

Set Hold

The Set Hold function locks the voltage output values on the present process value. This function can be used prior to calibration, or when removing the sensor from the process, to hold the output in a known state. Once HOLD is released, the outputs return to their normal state of following the process input.

The transfer out of HOLD is bumpless on the both analog outputs - that is, the transfer occurs in a smooth manner rather than as an abrupt change. An icon on the display indicates the HOLD state, and the HOLD state is retained even if power is cycled. Press ENTER to initiate user entry mode, and entire value will flash. Use the UP arrow key to modify the desired value, selections are ON for engaging the HOLD function, and OFF to disengage the function. Press ENTER to store the new value.

Fault List

The Fault List screen is a read-only screen that allows the user to display the cause of the highest priority failure.

The screen indicates the number of faults present in the system and a message detailing the highest priority fault present. Note that some faults can result in multiple displayed failures due to the high number of internal tests occurring. As faults are corrected, they are immediately cleared.

Faults are not stored; therefore, they are immediately removed if power is cycled. If the problem causing the faults still exists, however, faults will be displayed again after power is re-applied and a period of time elapses during which the diagnostic system re-detects them. The exception to this rule is the calibration failure. When a calibration fails, no corrupt data is stored. Therefore, the system continues to function normally on the data that was present before the calibration was attempted.
After 30 minutes or if power to the transmitter is cycled, the failure for calibration will be cleared until calibration is attempted again. If the problem still exists, the calibration failure will re-occur. Press ENTER to initiate view of the highest priority failure. The display will automatically return to normal after a few seconds.

**Sim Out**

The Sim Out function allows the user to simulate the dissolved oxygen level of the instrument to check the output settings. The user enters a ppm value directly onto the screen, and the output responds as if it were actually receiving the signal from the sensor.

This allows the user to check the function of attached monitoring equipment during set-up or troubleshooting. Escaping this screen returns the unit to normal operation. Press ENTER to initiate the user entry mode, and the right-most digit of the value will flash. Use arrow keys to modify desired value.

The starting display value will be the last read value of the input. The output will be under control of the SIM screen until the ESC key is pressed.

*Note:* If the HOLD function is engaged before the Sim Output function is engaged, the simulated output will remain the same even when the ESC key is pressed. Disengage the HOLD function to return to normal output.

**Auto-Off**

Enables the automatic shut-off feature for the instrument. If ON, the instrument will automatically shut-off in 30 minutes after no keys are pressed to save power. If OFF, the meter will stay powered continuously until either the operator turned instrument off, or the internal power switch on the battery board is turned OFF, or the battery voltage drops to the cut-off point (approximately 8-10 days on standard AA alkaline batteries if run continuously). Press ENTER to initiate user entry mode, and the entire value will flash. Use the UP arrow key to modify the desired display value. The choices are **OFF** and **ON**. Press ENTER to store the new value.
BackLight

The Back-light screen is used to set the operating conditions under which the backlight will turn on. The default is OFF, (Always Off). Other selections are AUTO, where the light comes on whenever any key is pressed. The light will automatically shut off if no key is pressed for 30 seconds, AL for Alarm, where the light comes on in alarm condition and flashes under a Fail condition, and ON (always on). Do not select ON as battery life will be greatly reduced.

Set Default

The Set Default function allows the user to return the instrument back to factory default data for all user settings. It is intended to be used as a last resort troubleshooting procedure.

All user settings are returned to the original factory values. Hidden factory calibration data remains unchanged. Press ENTER to initiate user entry mode and the value NO will flash. Use the UP arrow key to modify value to YES and press ENTER to reload defaults.
5.1 Overview and Methods

Calibration of the Q45C2 is required to accurately match the sensor characteristics to the monitor/analyzer. Since the output of the conductivity sensor does not degrade over time, it is typically only required that the sensor be calibrated at initial installation and then cleaned periodically to maintain proper system accuracy.

Although the system automatically compensates for foulants that build up on the electrode, it is important for the user to establish a periodic cleaning and calibration-check schedule for sensor maintenance to maintain high system accuracy.

Since the conductivity of a solution is greatly affected by temperature, proper settings for thermal compensation are critical for accurate operation. Before calibrating the instrument for the very first time, it is important to select the proper operating parameters in the configuration menus for temperature compensation methods. Also at initial installation, a temperature calibration must be performed before conductivity can be calibrated.

When using conductivity calibration standards for a wet calibration, take care not to inadvertently contaminate the reference solution; always thoroughly clean the sensor, rinsing off in tap water, and then finish rinsing in pure or de-ionized water. In addition, note that calibration solutions less than 100 μS or greater than 100 mS can be very unstable. Moving the sensor back and forth between different value conductivity reference solutions can quickly contaminate the solutions and render them inaccurate.

The system provides two methods of conductivity calibration: 1-point (wet calibration) and cell constant. These two methods are significantly different. In addition, a sensor zero-cal is used on initial installation to set the range zeros for the sensor used. See Sections 5.2 through 5.4 for brief descriptions of their uses.

5.2 1-Point Calibration Explained

The 1-point calibration method is generally known as the "grab sample" calibration method. In the 1-point calibration method, the sensor may be removed from the application and placed into a reference solution. It may also be left in the measurement process and calibrated by reference. The 1-point calibration adjusts the sensor slope to match the exact calibration point. Readings beyond that point are then extrapolated from the determined slope of the calibration line. Since the sensor slope does not degrade over time, frequent
re-calibration is unnecessary. Calibration accuracy can be optimized by calibrating with a reference solution which is close to the values typically measured.

5.3 Cell Factor Calibration Explained

The cell factor calibration method involves the user simply entering the known cell constant of the sensor. This value is labeled on the sensor along with the TC factor value. It is the recommended method of calibration for highest accuracy. It is also the easiest and fastest method of initial calibration because it involves no reference solutions. The Cell Factor method cannot be used if the sensor cable length has been altered from the length at which it was originally ordered. If the cable length has been altered, utilize the 1-point calibration method instead.

5.4 Zero Cal Calibration Explained

The sensor offset must be set for the system only on initial sensor installation, or when the cable length has been altered. The Zero Cal method establishes all of the sensor offset points for the instrument’s 6 ranges of operation.

5.5 Performing a 1-Point Calibration

This calibration method is intended to be used as an on-line calibration method or a wet-cal with reference solutions. During calibration, the system will display the current conductivity reading, and the user can manually enter a reference value from a reference solution bottle or a comparative reference instrument.

For wet calibrations, the user may use pre-made calibration references (also available from ATI) or a NaCl solution may be made using pure, dried NaCl crystals and one liter of high purity, de-ionized, CO\textsubscript{2}-free water as mixed in the table shown in Figure 8. All table data is at 25°C - therefore, the sensor must be at this temperature to calibrate properly using the table data. If another reference calibration solution is being used, be sure to note temperature of reference solution before calibration. Since the sensor must ideally be at the specified temperature, wet calibrations can be difficult to perform accurately.
During the 1-point calibration, the system will automatically pick the correct range for the calibration reference if the Q45C2 is in the AUTO range (see Section 5.2). It is recommended to leave the system in AUTO mode for this reason. If the Q45C2 is in a manual range, the user must be careful to calibrate with a solution that falls into the manual range selected. If the calibration solution is outside the manual range, an error will result. It may be desirable in some cases to calibrate in a manual range if the conductivity area of interest is close to a range change point.

### Procedure

1. Determine whether the calibration will be done on-line or with the sensor removed and placed into a reference solution. If the sensor is removed from the application, rinse and clean.

2. If the sensor has been removed and placed into a solution, allow sensor to temperature equilibrate with the solution as much as possible. With the sensor coming from an application that differs greatly in temperature, the user may have to wait as much as 20 minutes. If the sensor is on-line, the user may want to set the output HOLD feature prior to calibration to lock out any output fluctuations.

3. Scroll to the CAL menu section using the MENU key and press ENTER or the UP arrow key. **Cal Cond** will then be displayed.
4. Press the ENTER key and the lower line of the display will prompt the user to **Place the sensor in reference solution.** Press the ENTER key.

5. The screen will display the last measured conductivity value and a message will be displayed prompting the user for the lab value. The user must then modify the screen value with the arrow keys and press ENTER. The system then performs the proper checks.

6. The system now begins acquiring data for the calibration value. As data is gathered, the units for conductivity and temperature may flash. Flashing units indicate that this parameter is unstable. The calibration data point acquisition will stop only when the data remains stable for a pre-determined amount of time. This can be overridden by pressing ENTER. If the data remains unstable for 10 minutes, the calibration will fail and the message **Cal Unstable** will be displayed.

7. The screen will display the last measured conductivity value and a message will be displayed prompting the user for the lab value. The user must then modify the screen value with the arrow keys and press ENTER. The system then performs the proper checks.

8. If accepted, the screen will display the message **PASS** with the cell constant value, then it will return to the main measurement display. If the calibration fails, a message indicating the cause of the failure will be displayed and the FAIL icon will be turned on.

9. If this is a first-time installation or the sensor has just been replaced, also perform a zero-cal as described in Section 5.4.

5.6 Performing a Cell Factor Calibration

The Cell Factor calibration method utilizes a factory measured cell constant for the sensor. No solutions are required for a cell factor calibration.

The cell factor represents the physical electrode characteristics of the sensor. The surface area of the electrodes, the spacing of the electrodes and the sensor cable all contribute to cell factor of the sensor. By entering the factory cell value labeled on the sensor cable, the Q45C2 adjusts the factory calibration to match the characteristics of the specific sensor.
The cell factor value may be entered at any time, and it is not necessary to move or prepare the sensor in any way. Once this number is entered, the system is ready to use. Note that if the sensor cable length is adjusted (cut or extended) the cell factor data on the sensor label may be inaccurate for calibration. At this point, the 1-point calibration should be used.

**Procedure**

1. Scroll to the CAL menu section using the MENU key and press ENTER or the UP arrow key. Press the UP arrow key until **Cell Fact** is displayed.

2. Press the ENTER key. The screen will display a flashing value for the cell factor. Using the arrow keys, enter the cell factor number for the label on the sensor and press ENTER.

**5.7 Performing a Sensor Zero Calibration**

The sensor offset must be set for the system only on initial sensor installation, or when the cable length has been altered.

To begin the sensor zero cal, verify that the sensor is connected and clean and dry. It should be held in the air with the electrodes at least 1 foot away from any nearby objects.

**Procedure**

1. Scroll to the CAL menu section using the MENU key and press ENTER or the UP arrow key. **Zero Cal** will then be displayed.

2. Press the ENTER key. The screen will automatically scroll through all ranges and establish and store the proper zero points.

**5.8 Temperature Calibration**

The temperature input is factory calibrated for the highest accuracy. Temperature calibration is not recommended; however, it is provided for applications in which very long cable lengths are needed. For example, at 50 feet, readings may be off ±0.2 °C.

The temperature calibration sequence is essentially a 1-point offset calibration that allows adjustments of approximately ±5 °C.
The sensor temperature may be calibrated on line, or the sensor can be removed from the process and placed into a known solution temperature reference. In any case, it is critical that the sensor be allowed to reach temperature equilibrium with the solution in order to provide the highest accuracy. When moving the sensor between widely different temperature conditions, it may be necessary to allow the sensor to stabilize as much as one hour before the calibration sequence is initiated. If the sensor is on-line, the user may want to set the output HOLD (see Page 28) feature prior to calibration to lock out any output fluctuations.

Procedure

1. Scroll to the CAL menu section using the MENU key and press ENTER or the UP arrow key.

2. Press the UP arrow key until Cal Temp is displayed.

3. Press the ENTER key. The message Place sensor in solution then press ENTER will be displayed. Move the sensor into the calibration reference (if it hasn’t been moved already) and wait for temperature equilibrium to be achieved. Press ENTER to begin the calibration sequence.

4. The message Adjust temp value then press ENTER will be displayed, and the right-most digit will begin to flash, indicating that the value can be modified. Using the UP and LEFT arrow keys, modify the value to the known ref solution temperature. Adjustments up to ± 5 °C from the factory calibrated temperature are allowed. Press ENTER.

5. The calibration data gathering process will begin. The message Wait will flash as data is accumulated and analyzed. The °C or °F symbol may flash periodically if the reading is too unstable.

6. Once completed, the display will indicate PASS or FAIL. If the unit fails, the temperature adjustment may be out of range, the sensor may not have achieved complete temperature equilibrium, or there may be a problem with the temperature element. In the event of calibration failure, it is recommended to attempt the calibration again immediately.
5.9 TC Factor Calibration

This function is intended to give the user direct control of the temperature calibration offset value without having to proceed through the temperature calibration procedure. Sensor TC offset is a number that indicates the sensor RTD output at 0 ºC. Ideally, the sensor temperature output will be 0 ºC (1000 Ohms) under these conditions. Sensor offset is primarily the result of sensor RTD tolerance and connecting cable resistance. Large offsets are typically the result of large sensor cable lengths. A sensor reading of +1 ºC indicates that the sensor will output an uncalibrated reading of +1 ºC when placed in a theoretically perfect 0 ºC temperature bath. In other words, the offset shifts the entire sensor response curve up or down. Since the slope of an RTD is fixed and highly repeatable, the slope is not adjusted in this calibration.

Certain Q25 series sensors are labeled with a specific TC factor. Entering this factor directly allows the user to quickly calibrate the transmitter for the sensor being used without performing a time consuming full temperature calibration. However, if the sensor cable length is modified or a new sensor is used, a new TC factor must be entered or the user must perform a full temperature calibration. The default value for the TC factor is 7.50. Increasing this value increases the temperature reading and decreasing the value decreases the temperature reading. A change of approximately +0.1 is equivalent to +0.1 ºC. This function is directly related to the full temperature calibration function in that a new offset number is produced if a full temperature calibration has already been performed. If the TC factor is modified, it overrides any previous full temperature calibration data.

Procedure

Press ENTER to initiate user entry mode and the first digit will flash. Use arrow keys to modify value; range is 00.00 to 15.00. Press ENTER to save the new value.
Part 6 – System Maintenance

6.1 System Checks

1. If the FAIL icon is flashing on the display, check the Fault List to determine the cause of the failure. To access the Fault List, press the MENU/ESC key until the DIAG menu appears. Then press the UP arrow key until the Fault List appears. Press the ENTER key to access the Fault List, and the highest priority fault message will be displayed. For a list of all messages and possible causes/solutions, refer to Section 6.3.

2. Perform a one-point calibration prior to sensor installation.

3. Check sensor cable color to terminal strip markings.

4. For highly unstable behavior, remove sensor from the process and measure the process solution in a plastic beaker. If the reading now stabilizes, place wire in beaker solution and actual process solution to determine if a ground loop exists.

6.2 Instrument Checks

1. Remove sensor completely and connect 1100 Ohms from the yellow to black sensor input leads. Make sure the unit is configured for a Pt1000 thermal element and that the temperature is not in manual locked mode. The temperature reading should display approximately 25 °C and the conductivity reading should display approximately 0.0 uS.

2. With a DMM, measure the DC voltage from the white sensor lead connection to the black sensor lead connection. With the positive DMM lead on the white wire, the meter should read between -4.5 and -5.5 VDC.
6.3 Display Messages

The Q45 Series instruments provide a number of diagnostic messages that indicate problems during normal operation and calibration. These messages appear as prompts on the secondary line of the display or as items on the Fault List.

The following messages will appear as prompts:

<table>
<thead>
<tr>
<th>MESSAGE</th>
<th>DESCRIPTION</th>
<th>POSSIBLE CORRECTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Max is 200</td>
<td>Entry failed, maximum value allowed is 200.</td>
<td>Reduce value to $\leq$ 200</td>
</tr>
<tr>
<td>Min is 200</td>
<td>Entry failed, minimum value allowed is 200.</td>
<td>Increase value to $\geq$ 200</td>
</tr>
<tr>
<td>Cal Unstable</td>
<td>Calibration problem, data too unstable to calibrate.</td>
<td>Clean sensor, get fresh cal solutions, allow temperature and conductivity readings to fully stabilize, do not handle sensor or cable during calibration.</td>
</tr>
<tr>
<td>Slope HIGH</td>
<td>Sensor slope from calibration is greater than 110%.</td>
<td>Get fresh cal solutions, allow temperature and conductivity readings to fully stabilize, check for correct buffer values</td>
</tr>
<tr>
<td>Slope LOW</td>
<td>Sensor slope from calibration is less than 80%.</td>
<td>Clean sensor, get fresh cal solutions, allow temperature and conductivity readings to fully stabilize, check for correct buffer values</td>
</tr>
<tr>
<td>Out of Range</td>
<td>Input value is outside selected range of the specific list item being configured.</td>
<td>Check manual for limits of the function to be configured.</td>
</tr>
<tr>
<td>Locked!</td>
<td>Transmitter security setting is locked.</td>
<td>Enter security code to allow modifications to settings.</td>
</tr>
<tr>
<td>Unlocked!</td>
<td>Transmitter security has just been unlocked.</td>
<td>Displayed just after security code has been entered.</td>
</tr>
<tr>
<td>TC-F25 lock!</td>
<td>The TC selection is in F25 mode, locked at 25 ºC</td>
<td>Calibration and TC adjustment cannot be performed while the TC is in F25 mode. To allow access to TC calibrations, change TC mode from F25 (fixed 25) to SENS (sensor).</td>
</tr>
</tbody>
</table>
The following messages will appear as items on the Fault List:

<table>
<thead>
