Part 1 - Introduction

1.1 General

The Model Q46/76 is a versatile on-line monitoring system designed for the continuous measurement of turbidity in water. It is intended for continuous monitoring of potable water filter outlets, raw water inlets, or turbidity monitoring of wastewater effluent.

The full scale operating range of the system is 0-400 NTU. Actual display range is user programmable for 0-4, 0-40, or 0-400, and the system can also be programmed to display in units of PSL for applications where polystyrene latex spheres are the standard of measurement. The basic sensing element used in the turbidity system is an optical sensor measuring light scattered at 90 degrees to the transmitted beam. The sensor provides an auto-zeroing function to insure the highest sensitivity at very low turbidity levels.

Q46/76 Monitors are available in two electronic versions, an AC powered monitor with integral alarm relays and dual 4-20 mA output capability, and a 12-24 VDC unit with dual output and relays. Options are available to add either a third 4-20 mA output or 3 additional low power SPST relays. In addition, a digital output option for Profibus, Modbus, or Ethernet is available.

1.2 Standard System

The standard model Q46/76 system includes two components, the Q46 analyzer and an optical sensor with 30 ft. cable. For most filter effluent applications, the sensor must be used in a flow chamber to avoid errors due to ambient light. For wastewater effluent applications, a submersible sensor is available. When necessary, ATI’s Q-Blast air cleaning assembly can be used with the submersible sensor to reduce manual cleaning.

For connection of the sensor to the electronics, a 30’ cable is supplied. Up to an additional 100 feet of interconnect cable may be added using #07-0100 junction box.

1.3 Calibration Panel System

Q46T turbidity systems may be supplied as an assembled panel containing special components to simplify calibration. This assembly is optional and must be specified at the time of ordering. If this option is purchased, you will receive the system already mounted and wired on a 12”x24” non-metallic panel. Setup and programming of the electronics is the same as with a standard system but the procedure for calibration is different. Refer to Part 10 of this manual for specific details on the calibration panel assembly.
1.3 **Features**

- Standard Q46D electronic transmitters are designed to be a fully isolated instruments for operation from either 90-260 VAC or 12-24 VDC power supplies.

- Two 4-20 mA analog outputs are standard, and a third analog output is available as an option. One output may be configured for PID control, while other output is programmable to track either Turbidity or Temperature.

- Dry standard available for quick calibration verification.

- Digital communication option for Profibus-DP, Modbus-RTU, or Ethernet-IP.

- Output Hold, Output Simulate, Output Alarm, and Output Delay Functions. All forced changes in output condition include bumpless transfer to provide gradual return to on-line signal levels and to avoid system control shocks on both analog outputs.

- Units provide provides three SPDT relay outputs and two isolated analog outputs. Software settings for relay control include setpoint, deadband, phase, delay, and failsafe.

- Selectable Output Fail Alarm feature on Relay C allows system diagnostic failures to be sent to external monitoring systems.

- Large, high contrast, custom LCD display with LED back light provides excellent readability in any light conditions. The secondary line of display utilizes 5x7 dot matrix characters for clear message display two of four measured parameters may be on the display simultaneously.

- Diagnostic messages provide a clear description of any problem with no confusing error codes to look up. Messages are also included for diagnosing calibration problems.

- Security lock feature to prevent unauthorized tampering with transmitter settings. All settings can be viewed while locked, but they cannot be changed.

![Equipment bearing this marking may not be discarded by traditional methods in the European community after August 12 2005 per EU Directive 2002/96/EC. End users must return old equipment to the manufacturer for proper disposal.](image)
### 1.4 Q46/76 System Specifications

| Displayed Parameters | Main input, 0.001 to 400 NTU  
|                      | Sensor temperature, -10.0 to 50.0°C (23 to 122°F)  
|                      | Loop current, 4.00 to 20.00 mA  
|                      | Sensor slope/offset  
|                      | Model number and software version  
|                      | PID Controller Status  
| Main Parameter Ranges | Manual selection of one of the following display ranges, 0-4.000, 0-40.00, or 0-400.0 NTU  
| Power                | 90 - 260 VAC, 50/60 Hz., 10 VA Maximum  
|                      | or 12-24 VDC, 500 mA max.  
| Display              | 0.75” (19.1 mm) high 4-digit main display with sign  
|                      | 12-digit secondary display, 0.3” (7.6 mm) 5x7 dot matrix.  
|                      | Integral LED back-light for visibility in the dark.  
| Enclosure            | NEMA 4X, polycarbonate, stainless steel hardware,  
| Mounting Options     | Wall, pipe, or panel mount standard. Wall bracket suitable for either 1.5” or 2” I.D. U-Bolts for pipe mounting.  
| Conduit Openings     | Five ½” NPT openings, Adapter can be removed to provide a 1” NPT opening in the bottom of the enclosure. Gland seals provided but not installed.  
| Relays, Electromechanical | Three SPDT, 6 amp @ 250 VAC, 5 amp @ 24 VDC contacts. Software selection for setpoint, phase, delay, deadband, hi-lo alarm, and failsafe. A-B indicators on main LCD, and C indicator on lower display.  
| Analog Outputs       | Two 4-20 mA outputs. Output one programmable for NTU Turbidity or PID. Output 2 programmable for NTU or Temperature. Max load 450 Ohms for output 1 and 1000 ohms for output 2. Outputs ground isolated and isolated from each other. An additional 3rd analog option is available.  
| Output Isolation     | 600 V galvanic isolation  
| Optional Relays      | Three SPST, 1 amp @ 24 VDC. Software selection for setpoint, phase, delay, deadband, hi-lo alarm, and failsafe.  
| Ambient Temperature  | Analyzer Service, -20 to 60 °C (-4 to 140 °F)  
|                      | Sensor Service, 0 to 55°C (23 to 131 °F)  
|                      | Storage, -30 to 70 °C (-22 to 158 °F)  
| Ambient Humidity     | 0 to 95%, indoor/outdoor use, non-condensing to rated ambient temperature range |

2.1 General

All Q46 Series instruments offer maximum mounting flexibility. A bracket is included with each unit that allows mounting to walls or pipes. Choose a location that is readily accessible for calibrations and keep in mind that it will be necessary to use solutions during the calibration process. To take full advantage of the high contrast display, mount the instrument in a location where the display can be viewed from various angles and long distances.

Locate the instrument in close proximity to the point of sensor installation - this will allow easy access during calibration. The sensor-to-instrument distance should not exceed 100 feet (30 m). To maximize signal-to-noise ratio however, work with the shortest sensor cable possible. The standard cable length of the turbidity sensor is 30 feet.

![Figure 1 – Q46 Enclosure Dimensions](image-url)
2.2 Wall or Pipe Mount

A PVC mounting bracket with attachment screws is supplied with each transmitter (see Figure 2 for dimensions). The multi-purpose bracket is attached to the rear of the enclosure using the four flat head screws. The instrument is then attached to the wall using the four outer mounting holes in the bracket. These holes are slotted to accommodate two sizes of u-bolt that may be used to pipe mount the unit. Slots will accommodate u-bolts designed for 1½” or 2” pipe. The actual center to center dimensions for the u-bolts are shown in the drawing. Note that these slots are for u-bolts with 1/4-20 threads. The 1½” pipe u-bolt (2” I.D. clearance) is available from ATI in type 304 stainless steel under part number 47-0005.

![Wall or Pipe mount bracket diagram]
Figure 3 - Wall Mounting Diagram

Figure 4 - Pipe Mounting Diagram
2.3 Panel Mount, AC Powered Monitor

Panel mounting of an AC powered monitor uses the panel mounting flange molded into the rear section of the enclosure.

![Diagram of Panel Mounting](image)

**Figure 5 - Panel Mount Diagram**

Figure 5 provides dimensions for the panel cutout required for mounting. The panel mounting bracket kit must be ordered separately (part number 05-0068). This kit contains a metal retainer bracket that attaches to the rear of the enclosure, 4 screws for attachment of this bracket, and a sealing gasket to insure that the monitor flange provides a water tight seal when mounted to a panel.

The sealing gasket must first be attached to the enclosure. The gasket contains an adhesive on one side so that it remains in place. Remove the protective paper from the adhesive side of the gasket and slide the gasket over the back of the enclosure so that the adhesive side lines up with the back of the enclosure flange. Once in place, you can proceed to mount the monitor in the panel.
Part 3 – Sensor Installation

3.1 General

The majority of turbidity applications require the use of a flowcell assembly. This method is best when monitoring very low turbidity values, such as filter effluent. The flowcell used with ATI’s turbidity system is designed to eliminate ambient light effects, and to allow sample pressure to be maintained through the flowcell minimizing air bubble formation that can cause measurement errors. A bracket is supplied for mounting the flowcell to any flat surface.

3.2 Flowcell Mounting

Figure 6 provides flowcell dimensions. Note that the flowcell should always be mounted horizontally with the inlet on the bottom and outlet on the top.

Select a flowcell location with sufficient clearance below to allow installation of the inlet calibration valve to facilitate adjustment of the system after installation. See Figure 8 for the suggested tubing arrangement.

Figure 6 - Flowcell Dimensions
Figure 7 below provides a detail of how the turbidity sensor is installed in the flowcell assembly. During installation of the sensor, be sure that the O-ring is seated properly in the groove at the end of the flowcell assembly. Proper seating of that O-ring is critical to avoiding water leakage.

Figure 7 - Sensor / Flowcell Exploded View

Figure 8 below shows the recommended installation tubing arrangement for the turbidity system. A 3-way valve is supplied to facilitate calibration of the turbidity monitor. Install the valve as shown below so that turbidity standards can easily be introduced into the flowcell.
3.3 Raw Water Application

Turbidity monitoring of raw water with potentially high turbidity levels can be done using the standard flowcell with a slight modification, or the flow tee assembly as shown in Figure 10. If using the flowcell you need to remove the installed inlet and outlet fittings on the flow chamber, and replace with the larger fittings that came with the flowcell. These fittings accommodate 3/8" OD tubing. This flowcell is modified to bypass the flow control orifice and allow samples with high turbidity values to flow through the flowcell without plugging.
3.4 In-Line Installation

Turbidity sensors may be installed directly into a flowing pipe system provided that the water does not contain a lot of entrained air. A 1 ½” flow tee assembly is available for this purpose. It is best to install the sensor in a vertical pipe section with water flowing upward. This assures that air pockets cannot develop at the sensor. If installed in a horizontal run of pipe, place the sensor at the 3 or 9 o’clock position. Never mount the sensor on the top or bottom of the pipe. It is also good practice to install a bypass system around the sensor for maintenance and calibration purposes.

It should be noted that in-line installation is not recommended when normal turbidity levels will be below 0.5 NTU.

![Diagram of in-line installation]

*Figure 9 - 1-1/2” In-Line Installation*
Figure 10 - Flow Tee Exploded View
3.5 Submersible Installation

The standard turbidity sensor may also be used for submersion installations. **Note that turbidity sensors may be affected by bright ambient light conditions.** If submerged sensors are to be used outdoors, always use the Auto-Clean version of the sensor as it contains a light shield to minimize these effects. A special adapter is available for mounting the turbidity sensor to a 1” pipe. Figure 11 below shows a typical submersion mounting using ATI’s 00-1690 submersion mounting kit. This complete kit adapts to typical handrails. The pipe adapter only is part no. 00-1689 and is available separately when the handrail mounting kit is not required.

![Submersion Mounting Assembly Diagram](image)

*Figure 11 - Submersion Mounting Assembly*
Part 4 – Electrical Installation

4.1 General

The Q46 is powered in one of two ways, depending on the version purchased. The 12-24 VDC powered analyzer requires a customer supplied DC power supply. The 90-260 VAC version requires line power. Please verify the type of unit before connecting any power.

**WARNING:** Do not connect AC line power to the DC version. Severe damage will result.

**Important Notes:**

1. Use wiring practices that conform to national, state and local electrical codes. For proper safety as well as stable measuring performance, it is important that the earth ground connection be made to a solid ground point on TB7. The AC power supply in the transmitter contains a single 630mA slo-blo fuse (Wickmann/Littelfuse #372-0630). The fuse F1 is located adjacent to TB7 and is easily replaceable.

2. Do NOT run sensor cables or instrument 4-20 mA output wiring in the same conduit that contains AC power wiring. AC power wiring should be run in a dedicated conduit to prevent electrical noise from coupling with the instrumentation signals.

3. This analyzer must be installed by specifically trained personnel in accordance with relevant local codes and instructions contained in this operating manual. Observe the analyzer’s technical specifications and input ratings. Proper electrical disconnection means must be provided prior to the electrical power connected to this instrument, such as a circuit breaker - rated 250 VAC, 2 A minimum. If one line of the line power mains is not neutral, use a double-pole mains switch to disconnect the analyzer.

4. Repeated problems with lightning strikes damaging sensitive instrumentation are often attributed to poorly bonded earth grounds in the instrument power source. The protection schemes incorporated into this analyzer cannot operate to maximum efficiency unless the ground connection is at its’ absolute lowest impedance.

There is no standard ground resistance universally recognized. Many agencies recommend a ground resistance value of 5 ohms or less. The NEC recommends an impedance to ground of less than 25 ohms, and less than 5 ohms where sensitive equipment is installed. Power sources feeding sensitive instruments like the Q46H/79PR should have the lowest possible impedance to ground.
4.2 Electrical Connections

Verify the power supply requirement before installing. Also verify that power is fully disconnected before attempting to wire.

Q46 systems are supplied with 5 cable gland fittings for sealing cable entries.

Connect appropriate power to the matching designations on terminal strip TB7.

---

**WARNING**

Disconnect line power voltage BEFORE connecting line power wires to Terminal TB7 of the power supply. The power supply accepts only standard three-wire single phase power. The power supply is configured for 115 VAC or 230 VAC operation at the factory at time of order, and the power supply is labeled as such. Do NOT connect voltages other than the labeled requirement to the input.

---

The analog outputs from the system are present at terminals TB1 and TB2. The loop-load limitation in this configuration is 450 Ohms maximum for output 1 and 1000 ohms maximum for output 2. Also note that these two outputs are completely isolated from each other to insure that ground loops do not result from the connection of both outputs to the same device such as a PLC or DCS.

A ribbon cable connects the power supply assembly with the microprocessor assembly located in the front section of the enclosure. This cable may be unplugged from the front section of the monitor if service is needed, but should normally be left in place during installation.

The power strip, TB7, allows up to 12 AWG wire. A wire gauge of 16 AWG is recommended to allow for an easy pass-through into the ½” NPT ports when wiring.

AC or DC power should be brought into the enclosures through the bottom gland seal on the right side of the enclosure. This entry is directly above the power terminal blocks. Terminal blocks are pluggable, and can be removed for easy wire connection. See Figure 12 for TB7 Terminal Locations.
Figure 12 - AC Power Connections
4.3 Relay Connection

Three SPDT relays are provided on the power supply board. None of the relay contacts are powered. The user must supply the proper power to the contacts. For applications that require the same switched operating voltage as the Q46 (115 or 230 V), power may be jumped from the power input terminals at TB7. Relay wiring is connected at TB4, TB5, and TB6 as shown below. Note that the relay contact markings are shown in the NORMAL mode. Programming a relay for “Failsafe” operation reverses the NO and NC positions in this diagram.

![Figure 13 - Relay Contacts](image-url)
4.4 Optional Output/Relay Connection

TB2 is used to connect the optional 3-relay card (Error! Reference source not found.) OR the optional third analog output Out#3, (Figure 15). The Q46 can be configured for only one of these features, and the hardware for either option must be factory installed. Note that the optional 3 relays are for switching LOW POWER DC ONLY.

![Figure 14 - Optional Low Power Relay Wiring](image1)

![Figure 15 - Optional 3rd Analog Output Wiring](image2)
4.5 Direct Sensor Wiring

Sensor connections are made to a terminal block mounted on the front section of the monitor. The sensor cable can be quickly connected to the Q46 terminal strip by matching the wire colors on the cable to the color designations on the label in the monitor. Route signal cable away from AC power lines, adjustable frequency drives, motors, or other noisy electrical signal lines. Do not run sensor or signal cables in conduit that contains AC power lines or motor leads.

Figure 16 - Turbidity Sensor Connection
4.6 Remote Sensor Wiring

Generally it is best to keep the sensor close to the monitor. However, it is possible to mount the sensor as much as 100 feet from the monitor using a junction box and additional interconnect cable.

Note that the wire used for remote sensor connection does not contain the same conductor colors as the sensor wire. The wiring diagram below provides the information needed to connect a remote sensor using no. 07-0100 junction box.

![Remote Sensor Wiring Diagram]

Figure 17 - Remote Sensor Wiring
Part 5 – Configuration

5.1 User Interface

The user interface for the Q46 Series instrument consists of a custom display and a membrane keypad. All functions are accessed from this user interface (no internal jumpers, pots, etc.).

When power is first applied, you may notice that the display does not come on immediately. This is normal. There is a 5 second start routine that runs before the display illuminates. In addition, you will notice an occasional “flicker” of the display, occurring about twice an hour. This is the result of a display processor refresh program that insures long-term display integrity, and will always occur during normal operation of the instrument.

![User Interface Diagram]

*Figure 18 - User Interface*
5.11 Keys

All user configurations occur through the use of four membrane keys. These keys are used as follows:

**MENU/ESC**
To scroll through the menu section headers or to escape from anywhere in software. The escape sequence allows the user to back out of any changes in a logical manner. Using the escape key aborts all changes to the current screen and backs the user out one level in the software tree. The manual will refer to this key as either MENU or ESC, depending upon its particular function. In the battery-powered version of the Q46, this is also the ON button.

**UP (arrow)**
To scroll through individual list or display items and to change number values.

**LEFT (arrow)**
To move the cursor from right to left during changes to a number value.

**ENTER**
To select a menu section or list item for change and to store any change.

5.12 Display

The large custom display provides clear information for general measurement use and user configuration. There are three main areas of the display: the main parameter display, the secondary message line, and the icon area.

**Main Parameter**
During normal operation, the main parameter display indicates the present process input with sign and units. This main display may be configured to display any of the main measurements that the system provides. During configuration, this area displays other useful set-up information to the user.

![Main Parameter Display](image)

**Lower Line**
During normal operation, the lower line of the display indicates user-selected secondary measurements that the system is making. This also includes calibration data from the last calibration sequence and the transmitter model number and software version. During configuration, the lower line displays menu items and set-up prompts to the user. Finally, the lower line will display error messages when necessary. For a description of all display messages, refer to Section 10.31.

![Lower Line Display](image)
Icon Area

The icon area contains display icons that assist the user in set-up and indicate important states of system functions. The CAL, CONFIG, and DIAG icons are used to tell the user what branch of the software tree the user is in while scrolling through the menu items. This improves software map navigation dramatically. Upon entry into a menu, the title is displayed (such as CAL), and then the title disappears to make way for the actual menu item. However, the icon stays on.

HOLD

The HOLD icon indicates that the current output of the transmitter has been put into output hold. In this case, the output is locked to the last input value measured when the HOLD function was entered. HOLD values are retained even if the unit power is cycled.

FAIL

The FAIL icon indicates that the system diagnostic function has detected a problem that requires immediate attention. This icon is automatically cleared once the problem has been resolved.

Relay Area A/B

The relay area contains two icons that indicate the state of the system relays. Relay C is normally configured for FAIL indication, so it is only displayed on the lower MEASURE display line.

5.2 Software

The software of the Q46T is organized in an easy to follow menu-based system. All user settings are organized under five menu sections: Measure, Calibration [CAL], Configuration [CONFIG], Control [CONTROL] and Diagnostics [DIAG].

Note: The default Measure Menu is display-only and has no menu icon.
5.21 Software Navigation

Within the CAL, CONFIG, CONTROL, and DIAG menu sections is a list of selectable items. Once a menu section (such as CONFIG) has been selected with the MENU key, the user can access the item list in this section by pressing either the ENTER key or the UP arrow key. The list items can then be scrolled through using the UP arrow key. Once the last item is reached, the list wraps around and the first list item is shown again. The items in the menu sections are organized such that more frequently used functions are first, while more permanent function settings are later in the list. See Figure 19 for a visual description of the software.

Each list item allows a change to a stored system variable. List items are designed in one of two forms: simple single variable, or multiple variable sequences. In the single variable format, the user can quickly modify one parameter - for example, changing temperature display units from °F to °C. In the multiple variable sequence, variables are changed as the result of some process. For example, the calibration of oxygen generally requires more than one piece of information to be entered. The majority of the menu items in the software consist of the single variable format type.

Any data that may be changed will be flashing. This flashing indicates user entry mode and is initiated by pressing the ENTER key. The UP arrow key will increase a flashing digit from 0 to 9. The LEFT arrow key moves the flashing digit from right to left. Once the change has been completed, pressing ENTER again stores the variable and stops the flashing. Pressing ESC aborts the change and also exits user entry mode.

The starting (default) screen is always the Measure Menu. The UP arrow key is used to select the desired display. From anywhere in this section the user can press the MENU key to select one of the four Menu Sections.

The UP arrow icon next to all list items on the display is a reminder to scroll through the list using the UP arrow key.

To select a list item for modification, first select the proper menu with the MENU key. Scroll to the list item with the UP arrow key and then press the ENTER key. This tells the system that the user wishes to perform a change on that item. For single item type screens, once the user presses the ENTER key, part or all of the variable will begin to flash, indicating that the user may modify that variable using the arrow keys. However, if the instrument is locked, the transmitter will display the message Locked! and will not enter user entry mode. The instrument must be unlocked by entering the proper code value to allow authorized changes to user entered values. Once the variable has been reset, pressing the ENTER key again causes the change to be stored and the flashing to stop. The message Accepted! will be displayed if the change is within pre-defined variable limits. If the user decides not to modify the value after it has already been partially changed, pressing the ESC key aborts the modification and returns the entry to its original stored value.

In a menu item which is a multiple variable sequence type, once the ENTER key is pressed there may be several prompts and sequences that are run to complete the modification. The ESC key can always be used to abort the sequence without changing any stored variables.
Figure 19 - Software Map
5.22 Measure Menu [MEASURE]

The default menu for the system is the display-only menu MEASURE. This menu is a display-only measurement menu, and has no changeable list items. When left alone, the instrument will automatically return to this menu after approximately 30 minutes. While in the default menu, the UP arrow allows the user to scroll through the secondary variables on the lower line of the display. A brief description of the fields in the basic transmitter version is as follows:

**TRANSMITTER MEAS SCREENS:**

25.7°C Temperature display. Can be displayed in °C or °F, depending on user selection. A small "m" on the left side of the screen indicates the transmitter has automatically jumped to a manual 25C setting due to a failure with the temperature signal input.

% Signal Indicates the general condition of the sensor optics. The nominal value is 100% but the value will decrease if fouling of the sensor occurs. The value will rise if the flowcell is no longer full of water.

Slope = 100% Sensor output response vs. ideal calibration. This value updates after each calibration. High or low slope can generally indicate problems with the sensor or problems with the standard being used for calibration.

Zero Offset Sensor zero signal at 0.000 NTU as compared to factory default electronic zero. This value updates after a zero-calibration has been performed.

% Ext Light Indicates the background ambient light level detected by the sensor. This value is not meaningful when the sensor is inside the flowcell, but is useful when submersible turbidity sensors are used in open channels. Extremely high ambient light levels will trigger an alarm.

100% 20.00 mA PID Status screen (if enabled.) Shows the present controller output level on left, and actual transmitter current on the right. The controller can be placed in manual while viewing this screen by pressing and holding the ENTER key for 5 seconds until a small flashing "m" appears on the screen. At that point the controller output can be adjusted up or down using the UP and LEFT arrow keys. To return to automatic operation, press and hold the ENTER key for 5 seconds and the "M" will disappear.

#1 4.00 mA Analyzer output current # 1 (normally NTU)

#2 12.00 mA Analyzer output current # 2 (normally Temperature)

#3 20.00 mA Analyzer output current # 3 (if option included.)

Aux relay= D,E,F Auxiliary relay annunciators (if option included.)

Q46T vX.XX Transmitter software version number.

TU85XX vX.XX Sensor firmware version number.

I/F vX.XX Transmitter scaling card firmware version number.
Tcyc 24.0 hr  Automatic sensor cleaning frequency (displayed only when enabled in CONFIG Menu.

Note: A display test (all segments ON) can be actuated by pressing and holding the ENTER key while viewing the model/version number on the lower line of the display.

The MEASURE screens are intended to be used as a very quick means of looking up critical values during operation or troubleshooting.

5.23 Calibration Menu [CAL]

The calibration menu contains items for frequent calibration of user parameters. There are five items in this list: Cal Span, Cal Temp, Cal Zero, Cal Signal, and Set Range.

Cal Span  Provides adjustment of the turbidity value to match the standard being used for calibration. A 20 NTU standard is recommended. See Part 6 - Calibration for more details.

Cal Temp  The temperature calibration function allows the user to adjust the offset of the temperature response by a small factor of ±5°C.

Cal Zero  Provides adjustment of the turbidity value to 0 NTU when filtered sample is running through the flowcell. Sample must be filtered to less than 0.2 micron for adjustment of zero. See Part 6 - Calibration for more details.

Cal Signal  Provides adjustment of the "signal strength" indicator to 100% after cleaning of sensor. See Part 6 - Calibration for more details.

Set Range  Provides selection of the operating range. Ranges of 0-4.000, 0-40.00, or 0-400.0 NTU can be selected. The default range is 0-40.00, which is suitable for most filter outlet applications.

^L-Sig Filtr  Large Signal Filter. Range of entry is 5 to 200 seconds, default is 40 seconds. One Stage of two stage filter in the sensor. This is the filter time constant that applies to large span input deviations, for example, a 90% step change from 1.00 to 3.00 NTU.

^S-Sig Filtr  Small Signal Filter. Range of entry is 5 to 220 seconds, default is 120 seconds. One stage of two stage filter in the sensor. This is the filter time constant that applies to small span input deviations, for example, movement of +/- 0.1 NTU around a reading of 1.00 NTU.

5.24 Configuration Menu  [CONFIG]

The Configuration Menu contains all of the general user settings:

Entry Lock  This function allows the user to lock out unauthorized tampering with instrument settings. All settings may be viewed while the instrument is locked, but they cannot be modified. The Entry Lock feature is a toggle-type setting; that is, entering the correct code will lock the transmitter and entering the correct code again will unlock it. The code is preset at a fixed value. Press ENTER to initiate user entry mode and the first digit will flash. Use arrow keys to modify value. See Spare Parts List at the end of this
manual for the Q46T lock/unlock code. Press ENTER to toggle lock setting once code is correct. Incorrect codes do not change state of lock condition.

Contrast
This function sets the contrast level for the display. The custom display is designed with a wide temperature range and contains an LED back light so that the display is can be seen in the dark.

Press ENTER to initiate user entry mode, and the value will flash. Use arrow keys to modify the value; range is 0 to 8 (0 being lightest). Press ENTER to update and store the new value.

Main Units
Selects the engineering units for the measurement. Turbidity is normally displayed in "NTU" but can also be displayed in units of "PSL". This alternate unit is used in Japan where "polystyrene latex spheres" are the particles used for calibration instead of Formazin. To change from the default NTU units, press Enter, use the ↑ key to select PSL, and then press Enter.

Com Mode
Sets digital communication mode of analyzer. Optional digital communication card must be plugged into the power supply slot for this function to work. Press ENTER to initiate user entry mode, and the entire value will flash. Use the UP arrow key to modify the desired value; selections include 1-None, 2- P-DP for Profibus DP, 3 – Modbus, 4 – Ethernet IP. Press ENTER to store the new value.

Com Address
Sets bus address for digital communication mode of analyzer. Optional digital communication card must be plugged into the power supply slot for this function to work.

Press ENTER to initiate user entry mode, and the entire value will flash. Use the UP arrow key to modify the desired value. Range is 1-125. Press ENTER to store the new value.

Iout#1 Mode
This function sets analog output #1 to either track NTU turbidity or enables the PID controller to operate on the turbidity input. Press ENTER to initiate user entry mode, and the entire value will flash. Use the UP arrow key to modify the desired value; selections include 1- NTU turbidity or 2-PID for PID control. Press ENTER to store the new value.

Iout#2 Mode
This function sets analog output #2 for either temperature (default), NTU turbidity, or for Aux Units (mg/l or PSL). Press ENTER to initiate user entry mode, and the entire value will flash. Use the UP arrow key to modify the desired value; selections include 1-C/F for temperature, or 2-ppm NTU or r 3-mg/l or PSL. Press ENTER to store the new value.

Iout#3 Mode
OPTIONAL. This function sets analog output #3 for either temperature (default), NTU, or Aux. Units. Press ENTER to initiate user entry mode, and the entire value will flash. Use the UP arrow key to modify the desired value; selections include 1-C/F for temperature, or 2-ppm NTU or r 3-mg/l or PSL. Press ENTER to store the new value.
**Rly A Mode**

Relay A can be used in three different ways: as a setpoint control, as a fail alarm, or as a HI-LO alarm band. The three settings for Rly A Mode are **CON, FAIL** and **AL**.

The **CON** setting enables normal control operation for Relay A, with settings for setpoint, hysteresis, delay and phasing appearing in the CONTROL menu automatically. See Figure 21 for further details.

The **AL** setting allows two setpoints to be selected for the same relay, producing a HI-LO alarm band. In this mode, Relay A will trip inside or outside of the band, depending upon the Phase selected. See Figure 22 for further details.

The **FAIL** setting enables the fail alarm mode for Relay A. Relay A will then trip on any condition that causes the FAIL icon to be displayed on the LCD. Using this mode allows the User to send alarm indications to other remote devices.

**Relay B Mode**

Relay B can be used in two ways: as a setpoint control or as a fail alarm.

**Relay C Mode**

The settings for Relay B Mode are **CON, FAIL** and they are the same as those modes in relay A.

**Relay D Mode**

**OPTIONAL.** Relays D, E, and F can be used in two ways: as a setpoint control, or as a fail alarm. The two settings for Relay D, E, & F Mode are **CON** and **FAIL**.

**Temp Units**

This function sets the display units for temperature measurement. Press **ENTER** to initiate user entry mode, and the entire value will flash. Use the UP arrow key to modify the desired display value. The choices are **°F** and **°C**. Press **ENTER** to store the new value.

**5.25 Control Menu [CONTROL]**

The Control Menu contains all of the output control user settings. Note that PID menu items will not appear unless output 1 is configured for PID mode in the CONFIG menu.

**Set PID 0%**

If the PID is enabled, this function sets the minimum and maximum controller end points. Unlike the standard 4-20 mA output, the controller does not “scale” output values across the endpoints. Rather, the endpoints determine where the controller would normally force minimum or maximum output in an attempt to recover the setpoint (even though the controller can achieve 0% or 100% anywhere within the range.)

If the 0% point is lower than the 100% point, then the controller action will be “reverse” acting. That is, the output of the controller will increase if the measured value is less than the setpoint, and the output will decrease if the measured value is larger than the setpoint. Flipping the stored values in these points will reverse the action of the controller to “direct” mode.

The entry value is limited to a value within the range specified in “Set Range”, and the 0% and the 100% point must be separated by at least 1% of this range. Use the LEFT arrow key to select the first digit to be modified. Then use the UP and LEFT arrow keys to select the desired numerical value. Press **ENTER** to store the new value.
The measured value which the controller is attempting to maintain by adjusting output value. It is the nature of the PID controller that it never actually gets to the exact value and stops. The controller is continually making smaller and smaller adjustments as the measured value gets near the setpoint.

PID Prop

Proportional gain factor. The proportional gain value is a multiplier on the controller error (difference between measured value and setpoint value.) Increasing this value will make the controller more responsive.

PID Int

Integral is the number of “repeats-per-minute” of the action of the controller. It is the number of times per minute that the controller acts on the input error. At a setting of 2.0 rpm, there are two repeats every minute. If the integral is set to zero, a fixed offset value is added to the controller (manual reset.) Increasing this value will make the controller more responsive.

PID Deriv

Derivative is a second order implementation of Integral, used to suppress “second-order” effects from process variables. These variables may include items like pumps or mixers that may have minor impacts on the measured value. The derivative factor is rarely used in water treatment process, and therefore, it is best in most cases to leave it at the default value. Increasing this value will make the controller more responsive.

Set 4 mA

These functions set the main 4 and 20 mA current loop output points for the transmitter. The units displayed depend on the selection made in the CONFIG menu for Iout #1 Mode. Do not set the 20 mA setting above 400 NTU.

The value stored for the 4 mA point may be higher or lower than the value stored for the 20 mA point. The entry values are limited to values within the range specified in “Set Range”, and the 4 mA and the 20 mA point must be separated by at least 1% of this range. Use the LEFT arrow key to select the first digit to be modified. Then use the UP and LEFT arrow keys to select the desired numerical value. Press ENTER to store the new value.

*Set 4 mA #2

These functions set the second 4 mA and 20 mA current loop output points for the transmitter. The output may be set to track temperature (default), NTU, or the selected Aux Units of mg/l or PSL. The values stored for the 4 mA point may be higher or lower than the value stored for the 20 mA point.

The entry value is limited to a value between 0 and 55 °C if it is set for temperature, within the range specified in “Set Range” if the output is set to track NTU. The 4 mA and the 20 mA point must be at least 20 units away from each other. Press ENTER to initiate user entry mode, and the value will flash. Use arrow keys to modify value. Press ENTER to store the new value.

*Set 4 mA #3

OPTIONAL. These functions set the optional third 4 mA and 20 mA current loop output points for the analyzer. The output may be set to...
[temp/NTU/Aux] track temperature (default), NTU, or Aux Units. The values stored for the 4 mA point may be higher or lower than the value stored for the 20 mA point.

The entry value is limited to a value between 0 and 55 °C if it is set for temperature. The 4 mA and the 20 mA point must be at least 20 units away from each other. Press ENTER to initiate user entry mode, and the value will flash. Use arrow keys to modify value. Press ENTER to store the new value.

*A Setpoint

This function establishes the trip point for relay A. The entry value is limited to a value within the range specified in “Set Range”. Use the LEFT arrow key to select the first digit to be modified. Then use the UP and LEFT arrow keys to select the desired numerical value. Press ENTER to store the new value.

*A Hysteresis

This function establishes the hysteresis, or “deadband”, for Relay A. Hysteresis is most often used to control relay chattering; however, it may also be used in control schemes to separate the ON/OFF trip points of the relay. Press ENTER to initiate user entry mode, and the value will flash. Use the arrow keys to modify value. Press ENTER to store the new value.

*A Delay

This function places an additional amount of time delay on the trip point for relay A. This delay is in addition to the main delay setting for the controller. The entry value is limited to a value between 0 and 999 seconds. Press ENTER to initiate user entry mode, and the value will flash. Use arrow keys to modify value; range is 0 to 999 seconds. Press ENTER to store the new value.

*A Phasing

This function establishes the direction of the relay trip. When phase is HI, the relay operates in a direct mode. Therefore, the relay energizes and the LCD indicator illuminates when the oxygen value exceeds the setpoint. When the phase is LO, the relay energizes and the LCD indicator illuminates when the oxygen level drops below the setpoint. The failsafe setting does have an impact on this logic. The description here assumes the failsafe setting is OFF. Press ENTER to initiate user entry mode, and the entire value will flash. Use the UP arrow key to modify the desired value; selections include HI for direct operation or LO for reverse operation. Press ENTER to store the new value.

See Figure 20 below for a visual description of a typical control relay application.
When value rises to ≥ 1.000 ppm, relay closes.

When value falls to ≤ 0.950 ppm, relay opens.

Settings:
- Setpoint: 1.000 ppm
- Hyst: 0.050
- Delay: 000
- Failsafe: OFF

Figure 20 - Control Relay Example, Hysteresis & Phase Options

If Relay A Mode is set to Alarm Mode, AL, then the following settings will appear in the Config Menu list automatically. In this mode, two setpoints can be selected on the same relay, to create an alarm band. Phase HI selection causes the relay to energize outside of the band, and Phase LO causes the relay to energize inside of the band. This feature enables one relay to be used as a control relay while the other is used as a HI-LO Alarm relay at the same time. Setpoint A-LO must be set lower than Setpoint A-HI. When AL mode is first selected, Setpoint A-LO is defaulted to 0. Figure 21 is a visual description of a typical alarm relay application.

When value rises to ≥ 1.000 ppm, relay closes, until value falls back to < 0.950 ppm.
When value falls to < 0.500 ppm, relay closes until value rises to ≥ 0.550 ppm

Settings:
- Setpoint A-HI: 1.000 ppm
- Setpoint A-LO: .500 ppm
- Hyst A-HI: 0.050
- Hyst A-LO: .0.050
- Delay A-HI: 000
- Delay A-LO: 000

Figure 21 - Alarm Relay Example

If Relay B Mode is set to CON, then Relay B will function identically to Relay A. Relay B settings appear in the CONFIG menu list automatically.
If Relay C Mode is set to **CON** (see **Relay C Mode**), then Relay C will function identically to Relay A. Relay C settings appear in the **CONFIG** menu list automatically.

If Relay D, E, or F Mode is set to **CON** (see **Relay D,E,F Modes**), then the Relay will function identically to Relay A. Relay settings appear in the **CONFIG** menu list automatically.

### 5.26 Diagnostics Menu [DIAG]

The diagnostics menu contains all of the user settings that are specific to the system diagnostic functions, as well as functions that aid in troubleshooting application problems.

**Set Hold**

The Set Hold function locks the current loop output values on the present process value and holds relays in current status. This function can be used prior to calibration, or when removing the sensor from the process, to hold the output in a known state. Once HOLD is released, the outputs return to their normal state of following the process input. The transfer out of HOLD is bumpless on the both analog outputs - that is, the transfer occurs in a smooth manner rather than as an abrupt change. An icon on the display indicates the HOLD state, and the HOLD state is retained even if power is cycled. Press ENTER to initiate user entry mode, and entire value will flash. Use the UP arrow key to modify the desired value, selections are **ON** for engaging the HOLD function, and **OFF** to disengage the function. Press ENTER to store the new value.

The Set Hold function can also hold at an output value specified by the user. To customize the hold value, first turn the HOLD function on. Press the ESC key to go to the **DIAG** Menu and scroll to Sim Output using the UP arrow key. Press ENTER. Follow the instructions under Sim Output (see following page).

**Fault List**

The Fault List screen is a read-only screen that allows the user to display the cause of the highest priority failure. The screen indicates the number of faults present in the system and a message detailing the highest priority fault present. Note that some faults can result in multiple displayed failures due to the high number of internal tests occurring. As faults are corrected, they are immediately cleared.

Faults are not stored; therefore, they are immediately removed if power is cycled. If the problem causing the faults still exists, however, faults will be displayed again after power is re-applied and a period of time elapses during which the diagnostic system re-detects them. The exception to this rule is the calibration failure. When a calibration fails, no corrupt data is stored. Therefore, the system continues to function normally on the data that was present before the calibration was attempted.

After 30 minutes or if power to the transmitter is cycled, the failure for calibration will be cleared until calibration is attempted again. If the problem still exists, the calibration failure will re-occur. Press ENTER to
initiate view of the highest priority failure. The display will automatically return to normal after a few seconds.

**PID Timer**

This function sets a timer to monitor the amount of time the PID controller remains at 0% or 100%. This function only appears if the PID controller is enabled. If the timer is set to 0000, the feature is effectively disabled. If the timer value is set to any number other zero, a FAIL condition will occur if the PID controller remains at 0% or 100% for the timer value. If one of the relays is set to FAIL mode, this failure condition can be signaled by a changing relay contact.

Press ENTER to initiate user entry mode, and the entire value will flash. Use the UP arrow key to modify desired value; range of value is 0-9999 seconds. Press ENTER to store the new value.

**Sim Out**

The Sim Out function allows the user to simulate the oxygen level of the instrument in the user selected display range. The user enters a ppm value directly onto the screen, and the output responds as if it were actually receiving the signal from the sensor. This allows the user to check the function of attached monitoring equipment during set-up or troubleshooting. Escaping this screen returns the unit to normal operation. Press ENTER to initiate the user entry mode, and the right-most digit of the value will flash. Use arrow keys to modify desired value.

The starting display value will be the last read value of the input. The output will be under control of the SIM screen until the ESC key is pressed.

*Note:* If the HOLD function is engaged before the Sim Output function is engaged, the simulated output will remain the same even when the ESC key is pressed. Disengage the HOLD function to return to normal output.

**Fail Out #1**

This function enables the user to define a specified value that the main current output will go to under fault conditions. When the Relay Option Board is installed, the display will read Fail Out #1. When enabled to ON, the output may be forced to the current value set in Fail Val (next item.) With the Fail Out setting of ON, and a Fail Val setting of 6.5 mA, any alarm condition will cause the current loop output to drop outside the normal operating range to exactly 6.5 mA, indicating a system failure that requires attention.

Press ENTER to initiate user entry mode, and the entire value will flash. Use the UP arrow key to modify desired value; selections are ON, OFF. Press ENTER to store the new value.

**Fail Val #1**

Sets the output failure value for Iout#1. When Fail Out above is set to ON, this function sets value of the current loop under a FAIL condition. The output may be forced to any value between 4-20 mA. Press ENTER to initiate user entry mode, and the entire value will flash. Use the UP arrow key to modify desired value; selections are between 4mA, and 20mA. Press ENTER to store the new value.

**Fail Out #2**

This function sets the fail-mode of current loop output #2 under a FAIL condition. The settings and operation are identical to Fail Out for output #1.
Fail Val #2  This function sets the value of current loop output #2 under a FAIL condition. The settings and operation are identical to Fail Out for output #1.

*Fail Out #3  OPTIONAL. This function sets the fail-mode of current loop output #3 under a FAIL condition. The settings and operation are identical to Fail Out for output #1.

*Fail Val #3  OPTIONAL. This function sets the value of current loop output #3 under a FAIL condition. The settings and operation are identical to Fail Out for output #1.

Backlight  This function has three options. ON – On all the time, OFF – Off all the time, AL – Alarm (Default). This function flashes the backlight on and off whenever the Fail icon is displayed.

Start Delay  This function is designed to minimize control or alarm issues arising from temporary power loss. When power goes down, the monitor records the analog output values and the status of relays and PID functions. When power is restored, the analog values and relays will be held at the pre-power loss values for a defined period of time. This “start delay” may be programmed for periods from 0-9.9 minutes. This function is set to 0.0 minutes by default and must be activated by the user if desired by setting a positive time value.

*Failsafe  This function allows the user to set the optional system relays to a failsafe condition. In a failsafe condition, the relay logic is reversed so that the relay is electrically energized in a normal operating state. By doing this, the relay will not only change state when, for example, an oxygen limit is exceeded, but also when power is lost to the controller.

When failsafe is ON, the normally-open contacts of the relay will be closed during normal operation. In an attempt to make this configuration less confusing, the LCD icon logic is reversed with this setting, and the icon is OFF under this normal condition. Therefore, when the trip condition occurs, the closed N.O. contacts will be opened (relay de-energized), and the LCD icon will illuminate. In addition, a power fail would also cause the same contacts to open.

Fouling Alarm  Activates or disables the fouled sensor detector. This circuit detects the buildup of solids on the face of the sensor that can degrade the turbidity measurement. The options are ON—alarm is active, or OFF—alarm is disabled. The default is ON.

Dry Probe Alarm  Similar to the fouling alarm, this alarm is generated when the sensor is no longer in liquid. Loss of sample flow can cause this alarm to activate if the flowcell is drained of sample. The options are ON—alarm is active, or OFF—alarm is disabled. The default is ON.

Ext Light Alarm  The sensor can provide an alarm in the event that ambient light is high enough to cause measurement problems. This alarm is not useful for flowcell applications but can be of value if a submersible sensor is in use.
Options are **ON**– alarm active, or **OFF**– alarm disabled. The default is OFF.

**Cal Timer**

Defines the period of time **AFTER** completion of a calibration sequence in which the analog output remains in “hold”. After this period, the output is released and returns to normal.

**Set Default**

The Set Default function allows the user to return the instrument back to factory default data for all user settings or for just the calibration default. All user settings or the calibration settings are returned to the original factory values. Hidden factory calibration data remains unchanged. Press **ENTER** to initiate user entry mode and select either **CAL** or **ALL** with the UP arrow key. The default CAL routine will reset the zero offset to 0.0 nA and reset the slope to 100%. The default ALL routine will reset all program variables to factory default and should be used with care since it will change any user settings that were programmed in the field.
Part 6 – Calibration

6.1 Turbidity Calibration

Turbidity monitors will start to measure aqueous samples as soon as power is applied and sample is flowing through the flow chamber. Calibration of a turbidity system is normally required at start-up, but factory settings will be very close to actual, so it is often OK to start up the monitor without adjustment. Calibration requires only adjustment of the span of the instrument.

The turbidity sensor zero has been adjusted at the factory and user adjustment is normally not required. It is possible to adjust the zero of the Q46/76 by passing a sample through a filter with a pore size of 0.2 micron or smaller. Sample must be run through the filter for at least 30 minutes to be sure that all particles from the normal sample are diluted out of the flowcell. The procedure below will allow the adjustment of the system to zero on the filtered sample if desired, but this adjustment is normally unnecessary.

6.11 Cal Zero

Prior to attempting a zero calibration, it is best to remove the sensor from the flowcell and wipe the optical surfaces with a soft cloth to remove any buildup that could affect sensor performance. Once the sensor is clean, put it back into the flowcell and place a 0.2 micron filter in line with the incoming sample. Note that this should only be done if the incoming water prior to filtration has a turbidity of less than 1 NTU. Proceed as follows.

1. After the filtered water has been running for 30 minutes, press the Menu key to access the Cal Menu. Press the UP key until to access “Cal Zero”.

2. Press the Enter key and the bottom line will display a message asking that the sensor be placed in zero sample. Zero sample is already flowing so just press Enter again. The display will flash a “Wait” message. After a short period, you will be prompted to enter a value and the first digit of the display will flash. Normally, just press Enter to accept the default 0.000 NTU. However, it is possible to use this routine to offset you zero slightly in order to force low values to match a portable value. As an example, assume the monitor is reading 0.044 on your sample and a lab measurement is 0.090. If you run this procedure on this sample and enter 0.090, the monitor will calculate a zero offset and force the reading to the 0.090 value to match the lab. This can only be done for values less than 0.150 NTU.

3. After a short period, the monitor will zero the sensor and flash an “accepted” message indicating that the zero was successful. If the zero offset is too high, a “Cal Fail” message will appear and the “Fail” icon on the display will light up.

4. Once the zero adjustment is complete, remove the filter from the incoming sample line.

6.12 Cal Turbidity

Calibration of a Q46/76 turbidity monitor requires the use of a turbidity standard. Formazin standards are commonly used. Standards less than 10-20 NTU are not recommended.

Formazin turbidity standards can be prepared using reagent solutions available from ATI or other lab supply companies. The chemicals required are Turbidity Standard 1 (Formazin Sulfate, 1%,
ATI #51-0052 and Turbidity Standard 2 (Hexamethylenetetramine, 10%, ATI #51-0053). Stabilized turbidity standards available commercially may also be used for this purpose. ATI offers an EPA approved 20 NTU polymer standard that is safer than dealing with Formazin solutions. It is part number 51-0085. Contact your ATI representative to order.

Mixing a turbidity standard takes 24 hours. First, place 5 cc. of Turbidity Standard 1 and 5 cc. of Turbidity Standard 2 in a 100 cc volumetric flask. Allow to stand for 24 hours at about 25°C. Then dilute to 100 cc. with distilled water. This will provide a stock solution with a turbidity value of 400 NTU. This solution should be discarded after about 15 days.

Stock turbidity solution of 4000 NTU is also available from ATI (part #51-0077). This stock solution is good for 1 year and may be diluted to 20 NTU for calibration. A 1 liter volumetric flask and an accurate 5 ml. pipette should be used for dilution of the 4000 NTU standard.

To set the span of the turbidity monitor, dilute the 4000 NTU stock solution by 200:1 to give you a 20 NTU standard or dilute the 400 NTU standard by 20:1. Once your standard is prepared, proceed as follows. It is a good idea to remove the sensor from the flowcell and wipe the end of the sensor with a soft cloth or paper towel prior to calibration if the unit has been running for a few weeks.

1. Refer to Figure 8 on page 14. Turn off sample flow. The 3-way valve shown is supplied with a calibration kit. Remove the cap from the calibration port and connect the valve as shown. The valve can be left in place if desired as long as the “Off” handle is pointing to the fitting so that the flowcell is sealed during normal operation. As part of the system, a 60 cc syringe and 18” of silicon tubing is provided for use in feeding standard into the flowcell.

2. Prior to feeding standard, the flowcell must be drained. Turn the yellow valve handle so that the OFF position is facing to the left. This will allow water from the flowcell to drain out the bottom port of the valve. Note that you may need to elevate the drain tube from the flowcell so the flowcell drains.

3. Remove the plunger from the syringe and set it aside. Connect the silicon tubing from the syringe to the left port of the valve and turn the valve handle so the “Off” is facing down. Use the syringe body like a funnel, holding the bottom of the syringe slightly above the flowcell. Pour 20 NTU calibration solution into the funnel until you have fed about 80-100 cc into the flowcell. Then move the valve so the “Off” is facing to the right. That will seal the standard in the flowcell.

4. Press Menu to access the Cal Menu. Press the ↑ arrow to access “Cal Turbid”.

5. Press the Enter key and you will be prompted to “select range”. If you are already in the 40 NTU range, simply press Enter. If necessary, use the ↑ key to select the 0-40 range and then press Enter. If you changed range, you will see a “Wait” message while the new range is selected.

6. The lower line of the display will now prompt you to place the sensor in a standard. Since the flowcell is already full of 20 NTU standard, simply press Enter and you will be prompted to adjust the NTU value. Use the Up and Left keys to adjust each digit of the display to the value of your calibration solution (normally 20.00).

7. After the proper value is entered, press the Enter key and the display will flash “accepted”. Should the sensor determine that the entered value is outside its normal offset limits, a “Cal Fail” message will flash. Should this occur, a check of the calibration solution is required. Also check the sensor optical surface and wipe with a clean cloth before attempting another span adjustment.

8. After calibration, simply turn on the sample flow. The 20 NTU standard will be flushed out by the normal sample and the reading will return to actual sample value after a few minutes.
NOTE: The monitor calculates a slope % during the update. If the value you enter results in a slope of less than 70% or more than 130%, an error message will indicate this condition.

During calibration, the 4-20 mA output is held constant. As soon as you enter the “Cal Turbid” routine, the output hold is activated. The output will remain in hold until the new value has been entered and accepted. After that, the output hold will be released.

You may wish to maintain the output hold function for an additional period of time to allow the calibration fluid to be flushed out of the flowcell before releasing the output. If so, go to the DIAG menu and adjust the “Time” in the last routine. That routine defines the additional output hold time after conclusion of the calibration. A setting of 3-5 minutes is recommended if you want to avoid recording spikes at the end of a calibration.

6.2 Secondary Dry Standard

Periodic calibration using primary liquid standards are the best method of calibration. However, a dry secondary standard can be used more frequently to verify that the turbidity sensor calibration is stable. The dry standard is simply an optical assembly that provides a repeatable NTU value when a clean and dry sensor is inserted. The actual value is unique to a combination of sensor and dry standard and should be marked on a tag attached to the sensor.

The part number (60-0060) dry standard is an optional item and is not supplied with Q46/76 monitors. If this device was purchased with the monitor, the NTU value for the sensor must be established. This is very simple to do. After completion of a wet calibration as explained in 6.12, simply remove the sensor from the flowcell and dry it completely. Then place the sensor into the dry standard cylinder. Allow it to sit undisturbed for 2 or 3 minutes until the display shows a stable turbidity value. Record the serial number of the dry standard and the NTU value for that sensor on a tag. Attach that tag to the sensor for future reference. Three waterproof tags, markers, and attachment lanyards are supplied with the dry standard and additional tags and markers are available.

Figure 22 - Dry Standard Diagram
6.3 Temperature Calibration

The temperature calibration sequence is essentially a 1-point offset calibration that allows adjustments of approximately ± 5°C.

The sensor temperature may be calibrated on line, or the sensor can be removed from the process and placed into a known solution temperature reference. In any case, it is critical that the sensor be allowed to reach temperature equilibrium with the solution in order to provide the highest accuracy. When moving the sensor between widely different temperature conditions, it may be necessary to allow the sensor to stabilize as much as one hour before the calibration sequence is initiated. If the sensor is on-line, the user may want to set the output HOLD feature prior to calibration to lock out any output fluctuations.

1. Scroll to the CAL menu section using the MENU key and press ENTER or the UP arrow key.

2. Press the UP arrow key until Cal Temp is displayed.

3. Press the ENTER key. The message Place sensor in solution then press ENTER will be displayed. Move the sensor into the calibration reference (if it hasn’t been moved already) and wait for temperature equilibrium to be achieved. Press ENTER to begin the calibration sequence.

4. The calibration data gathering process will begin. The message Wait will flash as data is accumulated and analyzed. The °C or °F symbol may flash periodically if the reading is too unstable.

5. The message Adjust value - press ENTER will be displayed, and the right-most digit will begin to flash, indicating that the value can be modified. Using the UP and LEFT arrow keys, modify the value to the known ref solution temperature. Adjustments up to ± 5 °C from the factory calibrated temperature are allowed. Press ENTER.

Once completed, the display will indicate PASS or FAIL. If the unit fails, the temperature adjustment may be out of range, the sensor may not have achieved complete temperature equilibrium, or there may be a problem with the temperature element. In the event of calibration failure, it is recommended to attempt the calibration again immediately.
Part 7 – PID Controller Details

7.1 PID Description

PID control, like many other control schemes, is used in chemical control to improve the efficiency of chemical addition or control. By properly tuning the control loop that controls chemical addition, only the amount of chemical that is truly required is added to the system, saving money. The savings can be substantial when compared to a system which may be simply adding chemical at a constant rate to maintain some minimal addition under even the worst case conditions. The PID output controller is highly advantageous over simple control schemes that just utilize direct (proportional only) 4-20 mA output connections for control, since the PID controller can automatically adjust the "rate" of recovery based on the error between the setpoint and the measured value – which can be a substantial efficiency improvement.

The PID controller is basically designed to provide a "servo" action on the 4-20 mA output to control a process. If the user requires that a measured process stay as close as possible to a specific setpoint value, the controller output will change from 0% to 100% in an effort to keep the process at the setpoint. To affect this control, the controller must be used with properly selected control elements (valves, proper chemicals, etc.) that enable the controller to add or subtract chemical rapidly enough. This is not only specific to pumps and valves, but also to line sizes, delays in the system, etc.

This section is included to give a brief description of tuning details for the PID controller, and is not intended to be an exhaustive analysis of the complexities of PID loop tuning. Numerous sources are available for specialized methods of tuning that are appropriate for a specific application.

7.2 PID Algorithm

As most users of PID controllers realize, the terminology for the actual algorithm terms and even the algorithms themselves can vary between different manufacturers. This is important to recognize as early as possible, since just plugging in similar values from one controller into another can result in dramatically different results. There are various basic forms of PID algorithms that are commonly seen, and the implementation here is the most common version; The ISA algorithm (commonly referred to as the "ideal" algorithm.)

\[
output = P \left[ e(t) + \frac{1}{I} \int e(t)dt + D \frac{de(t)}{dt} \right]
\]

Where:
- \( output \) = controller output
- \( P \) = proportional gain
- \( I \) = integral gain
- \( D \) = derivative gain
- \( t \) = time
- \( e(t) \) = controller error (\( e = \) measured variable – setpoint)

*Figure 23 - ISA PID Equation*
The most notable feature of the algorithm is the fact the proportional gain term affects all components directly (unlike some other algorithms - like the “series” form.) If a pre-existing controller utilizes the same form of the algorithm shown above, it is likely similar settings can for made if the units on the settings are exactly the same. Be careful of this, as many times the units are the reciprocals of each other (i.e. reps-per-min, sec-per-rep.)

PID stands for “proportional, integral, derivative.” These terms describe the three elements of the complete controller action, and each contributes a specific reaction in the control process. The PID controller is designed to be primarily used in a “closed-loop” control scheme, where the output of the controller directly affects the input through some control device, such as a pump, valve, etc.

Although the three components of the PID are described in the setting area (section 6.25), here are more general descriptions of what each of the PID elements contribute to the overall action of the controller.

P Proportional gain. With no “I” or “D” contribution, the controller output is simply a factor of the proportional gain multiplied by the input error (difference between the measured input and the controller setpoint.) Because a typical chemical control loop cannot react instantaneously to a correction signal, proportional gain is typically not efficient by itself – it must be combined with some integral action to be useful. Set the P term to a number between 2-4 to start. Higher numbers will cause the controller action to be quicker.

I Integral gain. Integral gain is what allows the controller to eventually drive the input error to zero – providing accuracy to the control loop. It must be used to affect the accuracy in the servo action of the controller. Like proportional gain, increasing integral gain results in the control action happening quicker. Set the I term to a number between 3-5 to start (1-2 more than P). Like proportional gain, increasing the integral term will cause the controller action to be quicker.

D Derivative gain. The addition of derivative control can be problematic in many applications, because it greatly contributes to oscillatory behavior. In inherently slow chemical control process’, differential control is generally added in very small amounts to suppress erratic actions in the process that are non-continuous, such as pumps and valves clicking on and off. However, as a starting point for chemical process control, its best to leave the “D” term set to 0.

Based on these descriptions, the focus on tuning for chemical applications really only involves adjustment of “P” and “I” in most cases. However, increasing both increases the response of the controller. The difference is in the time of recovery. Although combinations of high “P’s” and low “I” will appear to operate the same as combinations of low “P’s” and high “I’s”, there will be a difference in rate of recovery and stability. Because of the way the algorithm is structured, large “P’s” can have a larger impact to instability, because the proportional gain term impacts all the other terms directly. Therefore, keep proportional gain lower to start and increase integral gain to achieve the effect required.

Many of the classical tuning techniques have the user start with all values at 0, and then increase the P term until oscillations occur. The P value is then reduced to ½ of the oscillatory value, and the I term is increased to give the desired response. This can be done with the Q46D controller, with the exception that the I term should start no lower than 1.0.

If it appears that even large amounts of integral gain (>20) don’t appreciably increase the desired response, drop I back to about 1.0, and increase P by 1.00, and start increasing I again. In most chemical control schemes, I will be approximately 3 times the value of P.
7.3 Classical PID Tuning

Unlike many high speed position applications where PID loops are commonly used, the chemical feed application employed by this instrument does not require intense mathematical exercise to determine tuning parameters for the PID. In fact, the risk of instability is far greater with overly tuned PID control schemes. In addition, many of the classical mathematical exercises can be damaging or wasteful in the use of chemicals when the process is bumped with large amounts of input error to seek a response curve. Because of this, the general adjustment guidelines described in section 8.2 are sufficient for almost all application tuning for this instrument. Beyond this, many sources are available for classical tuning methods.

7.4 Manual PID Override Control

The Q46 electronics is equipped designed to allow the user to take manual control of the PID output. This is often useful when starting up a control loop, or in the event that you wish to bump the system manually to measure system response time.

To access the manual PID control, you must be in the MEASURE mode of operation and you must have the PID output displayed on the lower line. This line will indicate “XX.X%  XX.X mA” with the X values simply indicating the current values. With this display on the screen, press and hold the ENTER key for about 5 seconds. You will see a small “m” show up between the % value and the mA value. This indicates you are now in manual mode.

Once in manual, you may increase the PID output by pressing the UP arrow or you may decrease the output by pressing the LEFT arrow. This will allow you to drive the PID output to any desired setting.

To revert to normal PID control, press and hold the ENTER key again until the “m” indicator disappears.

7.5 Common PID Pitfalls

The most common problem occurring in PID control applications involves the false belief that proper settings on only the PID controller can balance any process to an efficient level.

Close-loop control can only be effective if all elements in the loop are properly selected for the application, and the process behavior is properly understood. Luckily, the nature of simple chemical control process are generally slow in nature. Therefore, even a de-tuned controller (one that responds somewhat slow) can still provide substantial improvements to setpoint control. In fact, damaging oscillatory behavior is far more likely in tightly tuned controllers where the user attempted to increase response too much.

When deciding on a PID control scheme, it is important to initially review all elements of the process. Sticking valves, undersized pumps, or delays in reaction times associated with chemical addition can have a dramatic effect on the stability of the control loop. When controlling a chemical mix or reaction, the sensor should be placed in a location that ensures proper mixing or reaction time has occurred.
The easiest processes to control with closed-loop schemes are generally linear, and symmetrical, in nature. For example, controlling level in tank where the opening of valve for a fixed period of time corresponds linearly to the amount that flows into a tank. Chemical control processes can be more problematic when the nature of the setpoint value is non-linear relative to the input of chemical added. For example, D.O. control of a process may appear linear only in a certain range of operation, and become highly exponential at the extreme ranges of the measuring scale. In addition, if a chemical process is not symmetrical, that means it responds differentially to the addition and subtraction of chemical. It is important in these applications to study steady-state impact as well as step-change impact to process changes. In other words, once the process has apparently been tuned under normal operating conditions, the user should attempt to force a dramatic change to the input to study how the output reacts. If this is difficult to do with the actual process input (the recommended method), the user can place the control in manual at an extreme control point such as 5% or 95%, and release it in manual. The recovery should not be overly oscillatory. If so, the loop needs to be de-tuned to deal with that condition (reduce P and/or I.)
Part 8 – System Maintenance

8.1 General

The Q46/76 Turbidity Monitor will generally provide unattended operation over long periods of time. With proper care, the system should continue to provide measurements indefinitely. For reliable operation, maintenance on the system must be done on a regular schedule. Keep in mind that preventive maintenance on a regular schedule is much less troublesome than emergency maintenance that always seems to come at the wrong time.

8.2 Analyzer Maintenance

No unusual maintenance of the analyzer is required if installed according to the guidelines of this operating manual. If the enclosure door is frequently opened and closed, it would be wise to periodically inspect the enclosure sealing gasket for breaks or tears.

8.3 Sensor Maintenance

Sensor maintenance is limited to simple cleaning of the optical surfaces. In general, wiping with a soft cloth is all that’s needed. The optical surfaces can also be cleaned with a household glass cleaner or a surface cleaner. Never use abrasive pads on the optical surfaces.

In some applications, the sensor might accumulate iron and manganese deposits that precipitate from the water after chlorination. Should this occur, cleaning the sensor by soaking in solution of a commercial iron remover such as “Red-B-Gone” will quickly remove deposits.

The lenses on the sensor are made of acrylic. Be careful not to scratch these surfaces when handling the sensor. Severe scratches can cause irreparable damage.
Part 9 – Troubleshooting

9.1 General

The information included in this section is intended to be used in an attempt to quickly resolve an operational problem with the system. During any troubleshooting process, it will save the most time if the operator can first determine if the problem is related to the analyzer, sensor, or some external source. Therefore, this section is organized from the approach of excluding any likely external sources, isolating the analyzer, and finally isolating the sensor. If these procedures still do not resolve the operational problems, any results the operator may have noted here will be very helpful when discussing the problem with the factory technical support group.

9.2 External Sources of Problems

To begin this process, review the connections of the system to all external connections.

1. Verify the analyzer is earth grounded. For all configurations of the analyzer, an earth ground connection MUST be present for the shielding systems in the electronics to be active. Grounded conduit provides no earth connection to the plastic enclosure, so an earth ground wiring connection must be made at the power input terminal strip. Use the special “shield terminal” stub on the power supply board for optimum sensor cable shield grounding.

2. Verify the proper power input is present. Check instrument label to verify your unit is either 100-240 VAC or 12-24 VDC.

3. Verify the loads on any 4-20 mA outputs do not exceed the limits in the Instrument Specifications. During troubleshooting, it is many times helpful to disconnect all these outputs and place wire-shorts across the terminals in the instrument to isolate the system and evaluate any problems which may be coming down the analog output connections.

4. Do not run sensor cables or analog output wiring in the same conduits as power wiring. If low voltage signal cables must come near power wiring, cross them at 90° to minimize coupling.

5. If rigid conduit has been run directly to the Q46 enclosure, check for signs that moisture has followed conduit into the enclosure.

6. Check for ground loops. Although the sensor is electrically isolated from the process water, high frequency sources of electrical noise may still cause erratic behavior in extreme conditions. If readings are very erratic after wiring has been checked, check for a possible AC ground loop by temporarily placing the sensor into a bucket of water.

7. On relay based systems, check the load that is connected to the relay contacts. Verify the load is within the contact rating of the relays. Relay contacts which have been used for higher power AC current loads may become unsuitable for very low signal DC loads later on because a small amount of pitting can form on the contacts. If the load is highly inductive (solenoids, motor starters, large aux relays), note that the contact rating will be de-rated to a lower level. Also, due to the large amount of energy present in circuits driving these types of loads when they are switched on or off, the relay wiring placement can
result in electrical interference for other devices. This can be quickly resolved by moving wiring, or by adding very inexpensive snubbers (such as Quencharcs) to the load.

8. Carefully examine any junction box connections for loose wiring or bad wire stripping. If possible, connect the sensor directly to the analyzer for testing.

9. Check sensor for fouling. Look closely for signs of grease or oil which may be present. Sensor fouling can be corrected by cleaning optical surfaces with a soft cloth.

9.3 Analyzer Tests

1. Disconnect power and completely disconnect all output wiring coming from the analyzer. Remove sensor wiring, relay wiring, and analog output wiring. Re-apply power to the analyzer. Verify proper voltage (115 or 230 VAC) is present on the incoming power strip of the analyzer, and that the analyzer power label matches the proper voltage value.

2. If analyzer does not appear to power up (no display), remove power and check removable fuse for continuity with a DVM.

3. Using a DVM, check the voltage across the BLUE and WHITE wires coming from the power supply board in the base of the enclosure. FIRST, disconnect any wiring going to Iout#1. Then, verify voltage across these wires is about 16-18 VDC when still connected to the terminal strip on the front half of the enclosure. If the BLUE and WHITE wires are not connected to the terminal strip on the front half of the enclosure, the voltage across them should measure about 29 VDC.

4. If analyzer does power up with a display, use the "Simulate" feature to check operation of the analog outputs (and relays contacts with a DVM.)

5. Check sensor power circuits. With a DVM, verify between -4.5 and -5.5 VDC from sensor connection terminals WHITE (+) to BLACK (-). Then verify between +4.5 and +5.5 VDC from GREEN (+) to BLACK (-).

6. Check TC drive circuit. Place a wire-short between the RED and BLACK sensor terminals. With a DVM, measure the voltage between the BLACK (-) and BROWN (+) sensor terminals to verify that the TC drive circuit is producing about -4.6 to -5.5 VDC open-circuit. Remove DVM completely and connect a 1000 Ohm resistor across the BLACK to BROWN terminals. The temperature reading on the front LCD should display approximately 0°C and the dissolved oxygen reading should display approximately 0 ppm.
### 9.31 Display Messages

The Q46 Series instruments provide a number of diagnostic messages which indicate problems during normal operation and calibration. These messages appear as prompts on the secondary line of the display or as items on the Fault List.

Part 10 - Calibration Panel

10.1 General

The Q46T calibration panel is an assembly designed to simplify testing and calibration of the Q46T turbidity monitor. This panel option provides special valving and turbidity standard feed system so that calibrations can be done quickly and efficiently using either Formazin or synthetic turbidity standards. The assembly is intended for use on filter effluent applications or other samples where turbidity normally does not exceed 40 NTU.

Note that this assembly is not a good choice for use in “raw water” applications. The high turbidity values often found in those applications can quickly plug the flow regulator and/or the rotameter.

Each panel assembly provides the following items:

1. An inlet ball valve to turn sample flow on and off
2. A ball valve to allow process water to be drained from the flowcell. Note that the inlet and drain valves are on a tee below the flowcell
3. An acrylic chamber for feeding turbidity standards into the flowcell.
4. A two way calibration standards feed valve to control introduction of standard to the flowcell.
5. A rotameter on the outlet of the panel to provide positive indication of sample flow during normal turbidity operation.
6. An instructional placard on the panel providing complete calibration instructions.

Q46 turbidity panels are supplied with a “speed fit” type of fittings for both inlet and outlet. That same type of fitting is used on the drain valve, although often no tubing is connected. Those fittings are suitable for connection of ¼” O.D. sample tubing. A 10 ft. length of tubing and a ¼” NPT tubing adapter are supplied with the panel for installation.

Figure 1 shows the layout of the panel along with dimensional data.
1. Close Valve A
2. Remove clear chamber cover
3. Place container below Valve B
4. Open Valves B & C and allow to drain.
5. Close Valves B & C.
6. Fill clear chamber ¾ full with NTU standard.
7. Open Valve C and allow flowcell to fill.
8. Allow Q46 value to stabilize for 3 minutes.
9. Adjust Q46 to standard value if needed.
10. Close Valve C and open Valve A.

**Figure 25 - Typical Panel Assembly**
10.2 Installation

Installation of the panel system is simple.

1. Mount the panel to the wall or other support using the 4 corner holes.

2. Connect the water sample to the inlet fitting attached to the left hand ball valve below the flowcell. The ball valve should remain closed.

3. Connect your drain tubing to the drain fitting on the rotameter and route the tubing to a suitable drain in your installation site.

4. Check that the sensor is inserted in the flowcell and the retaining ring is in the proper position.

10.3 Startup

Once steps 1-4 above are complete, turn on the sample supply to the panel and open the ball valve. Water will begin to flow immediately. The flow indicator should show a flow rate of about 6 GPH. There are no adjustments to be made in this part of the system. The flow is controlled by a fixed flow regulating device that is part of the flowcell outlet fitting.

Allow water to flow through the system for 15-30 minutes while everything stabilizes. The turbidity monitor should be showing a reasonably steady value. Assuming the water is filter effluent, turbidity values will normally be below 1 NTU.

10.4 Calibration

To calibrate the turbidity monitor using the standards feed system, follow these steps. Note that these instructions are included on the placard in the center of the panel assembly.

1. Close valve “A”. This is the sample inlet valve

2. Remove clear chamber cover. This insures flowcell can drain completely.

3. Place container below valve “B”. This is to collect water draining from the flowcell.

4. Open valves “B” and “C” and allow flowcell to drain.

5. Close valves “B” and “C” after flowcell is drained completely.

6. Fill clear chamber ¾ full of turbidity standard.

7. Open vales “C” to allow flowcell to fill with standard.
8. Allow Q46T reading to stabilize for about 3 minutes.

9. Adjust the Q46T to the NTU value of your standard if necessary. Note that a reading within 5% of the standard value indicates that no adjustment is needed.

10. Close valve “C” and then open valve “A”. Be sure valve C is closed first or you will eject water through the clear chamber.

11. Replace the cover on the clear chamber to avoid dust or dirt contaminating standards.

10.5 Flow Regulator Maintenance

As mentioned previously, the outlet fitting from the flowcell contains a flow control device. This device is intended to control the sample flow at about 0.45 LPM. It is not a precision device and flow can vary by 10 or 15% but this does not affect turbidity values.

The flow regulator can accumulate solids from the sample over long periods of time. You may clean this device by removing the fitting from the flowcell and running water through the fitting in the reverse direction. This should dislodge particulate and restore normal operation.

Note that this flow control fitting is inexpensive and it is useful to have a spare or two available so that monitor operation can be restored without need to clean the fitting first. The fitting is part number 03-0553.

PRODUCT WARRANTY

Analytical Technology, Inc. (Manufacturer) warrants to the Customer that if any part(s) of the Manufacturer's equipment proves to be defective in materials or workmanship within the earlier of 18 months of the date of shipment or 12 months of the date of start-up, such defective parts will be repaired or replaced free of charge. Inspection and repairs to products thought to be defective within the warranty period will be completed at the Manufacturer's facilities in Collegeville, PA. Products on which warranty repairs are required shall be shipped freight prepaid to the Manufacturer. The product(s) will be returned freight prepaid and allowed if it is determined by the manufacturer that the part(s) failed due to defective materials or workmanship.

This warranty does not cover consumable items, batteries, or wear items subject to periodic replacement including lamps and fuses.

Gas sensors carry a 12 month from date of shipment warranty and are subject to inspection for evidence of misuse, abuse, alteration, improper storage, or extended exposure to excessive gas concentrations. Should inspection indicate that sensors have failed due to any of the above, the warranty shall not apply.

The Manufacturer assumes no liability for consequential damages of any kind, and the buyer by acceptance of this equipment will assume all liability for the consequences of its use or misuse by the Customer, his employees, or others. A defect within the meaning of this warranty is any part of any piece of a Manufacturer's product which shall, when such part is capable of being renewed, repaired, or replaced, operate to condemn such piece of equipment.

This warranty is in lieu of all other warranties (including without limiting the generality of the foregoing warranties of merchantability and fitness for a particular purpose), guarantees, obligations or liabilities expressed or implied by the Manufacturer or its representatives and by statute or rule of law.

This warranty is void if the Manufacturer's product(s) has been subject to misuse or abuse or has not been operated or stored in accordance with instructions, or if the serial number has been removed.

Analytical Technology, Inc. makes no other warranty expressed or implied except as stated above.
